

Antimicrobial susceptibility

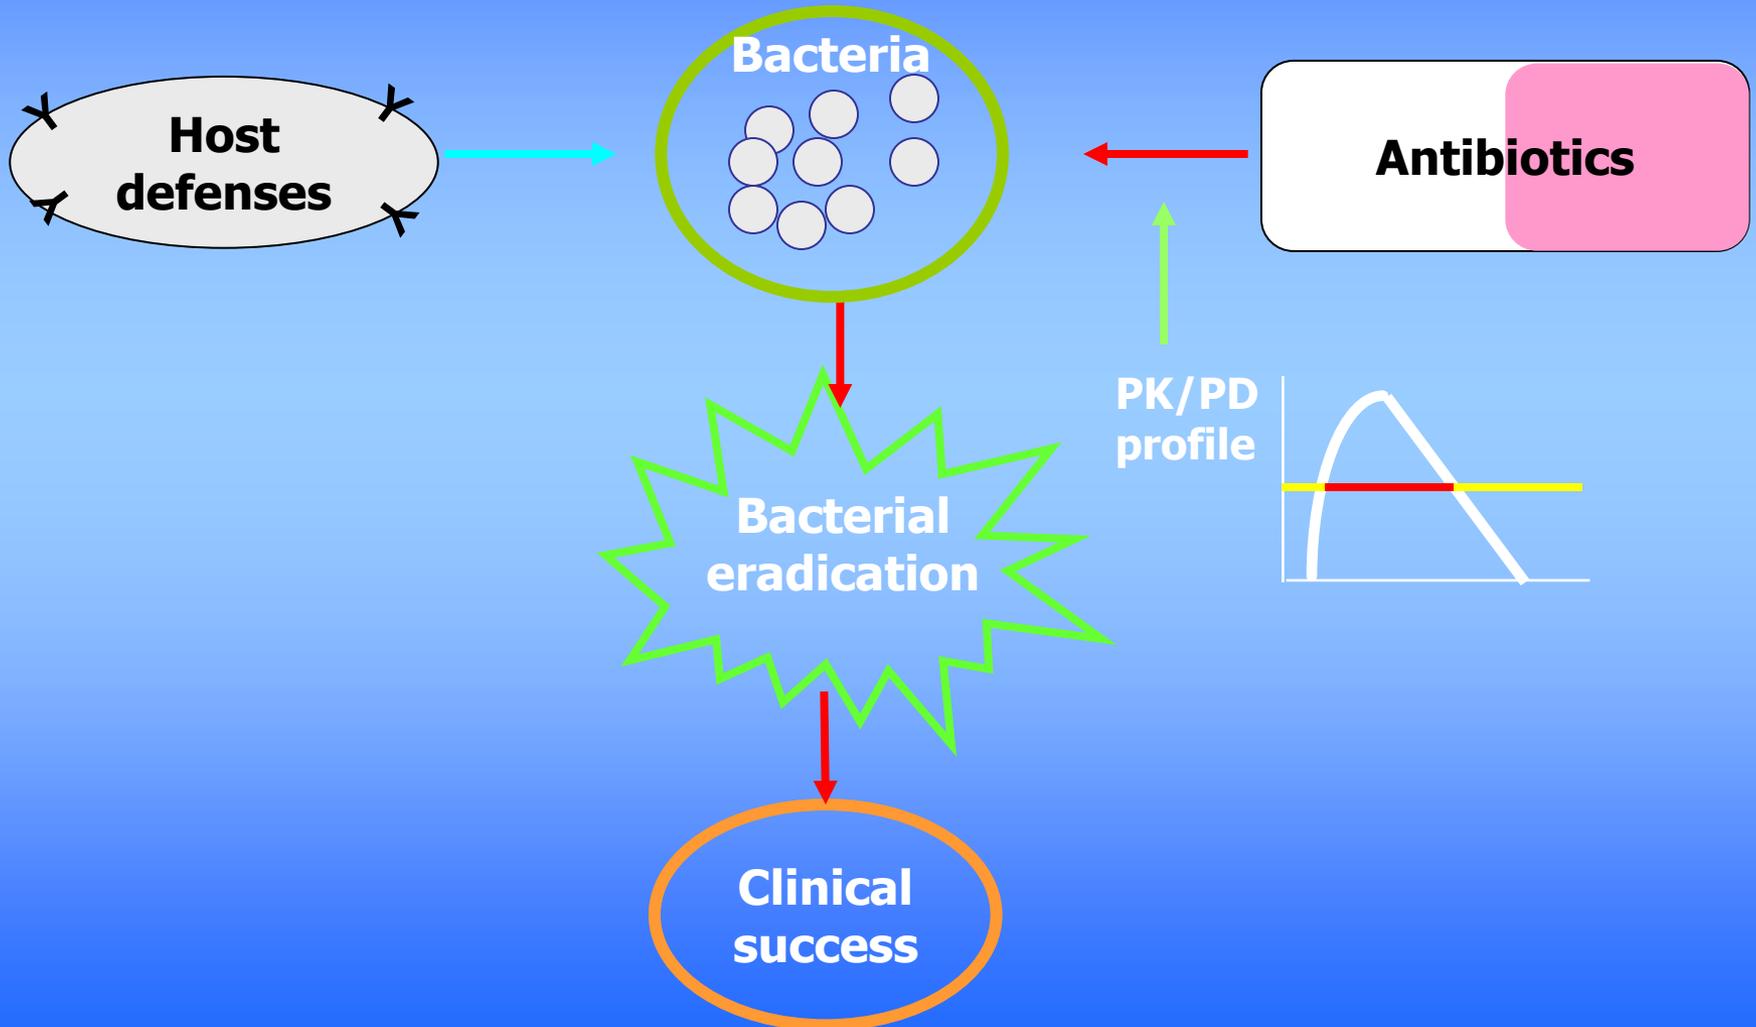

Michael R. Jacobs, MD, PhD

Case Western Reserve University

University Hospitals of Cleveland

Cleveland, OH

Determinants of clinical success

Determining “potency” of antimicrobial agents

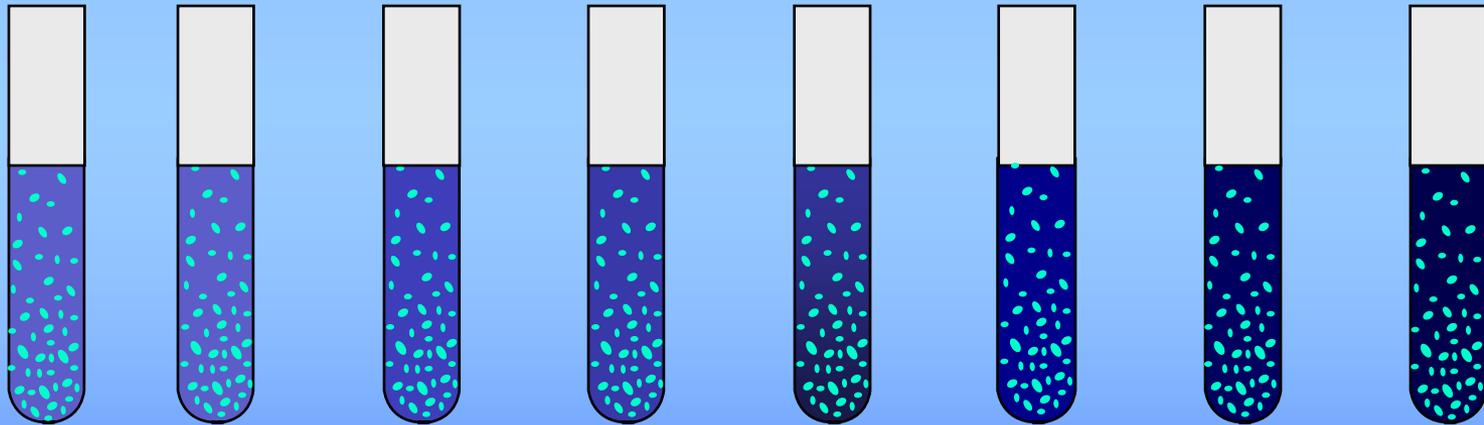

- Minimal inhibitory concentration (MIC) determination
- Minimal bactericidal concentration (MBC) determination
- Subinhibitory and post-antibiotic effects (SME and PAE)
- Interpreting MICs
 - MIC₅₀ and MIC₉₀ values
 - MIC distributions
 - Interpretative breakpoints

Minimal inhibitory concentration (MIC): measure of “potency”

- **MICs** are the most common measures used for the evaluation of antimicrobial activity
- **MICs** are *in vitro* measurements:
 - **the antibiotic concentration required to completely inhibit visible growth in a test tube**
 - **Bacterial inoculum, medium and incubation time are standardized**
 - **Antibiotic concentration is constant**

Minimal inhibitory concentration

Known quantity of bacteria placed into each tube

0 0.25 0.5 1.0 2.0 4.0 8.0 16
µg/mL µg/mL µg/mL µg/mL µg/mL µg/mL µg/mL µg/mL

Increasing antibiotic concentration

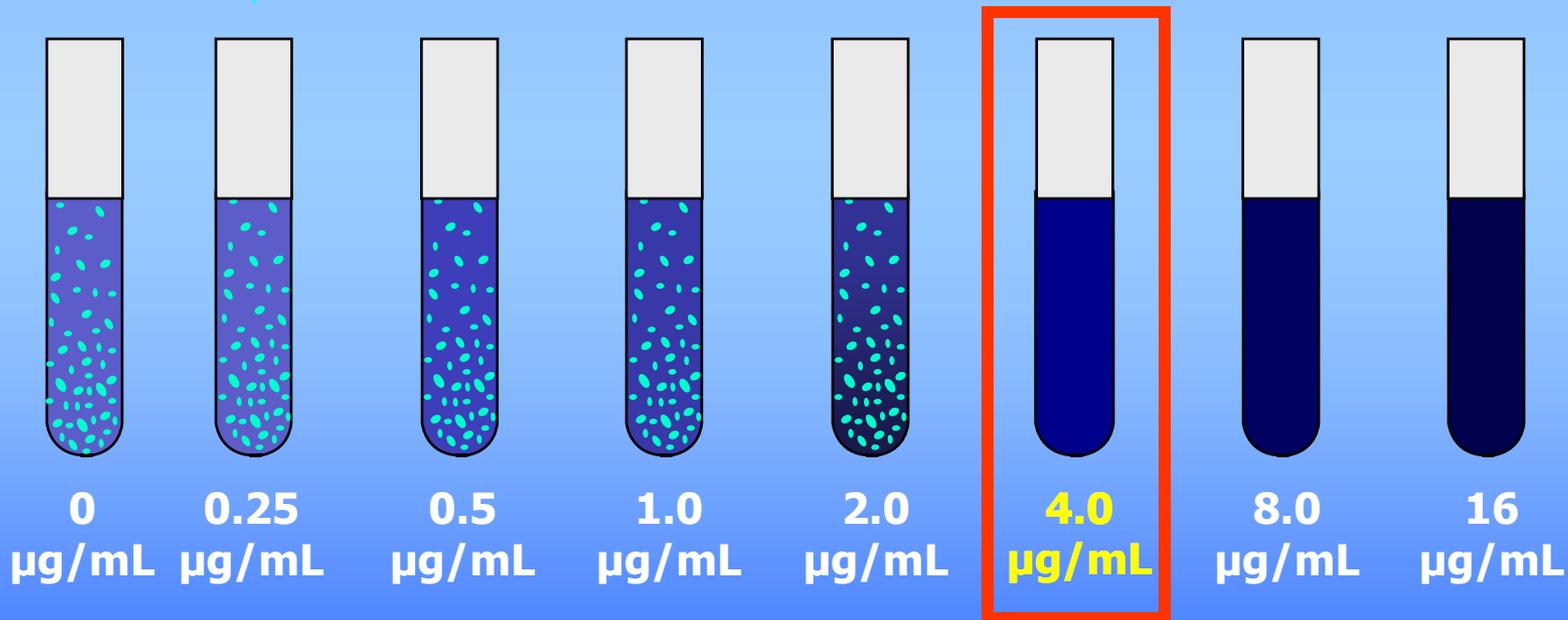

Minimal inhibitory concentration

Known quantity of bacteria placed into each tube

Lowest concentration of an antimicrobial that results in the inhibition of visible growth of a microorganism

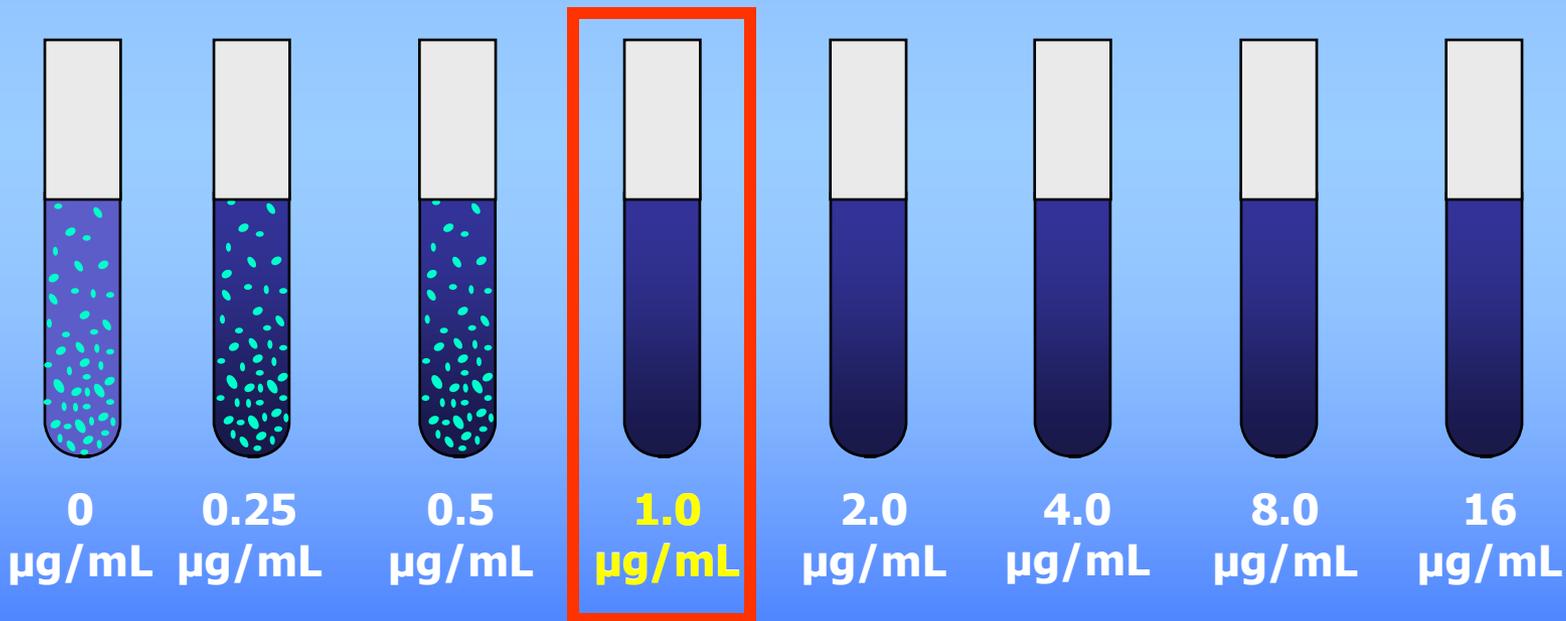

Increasing antibiotic concentration

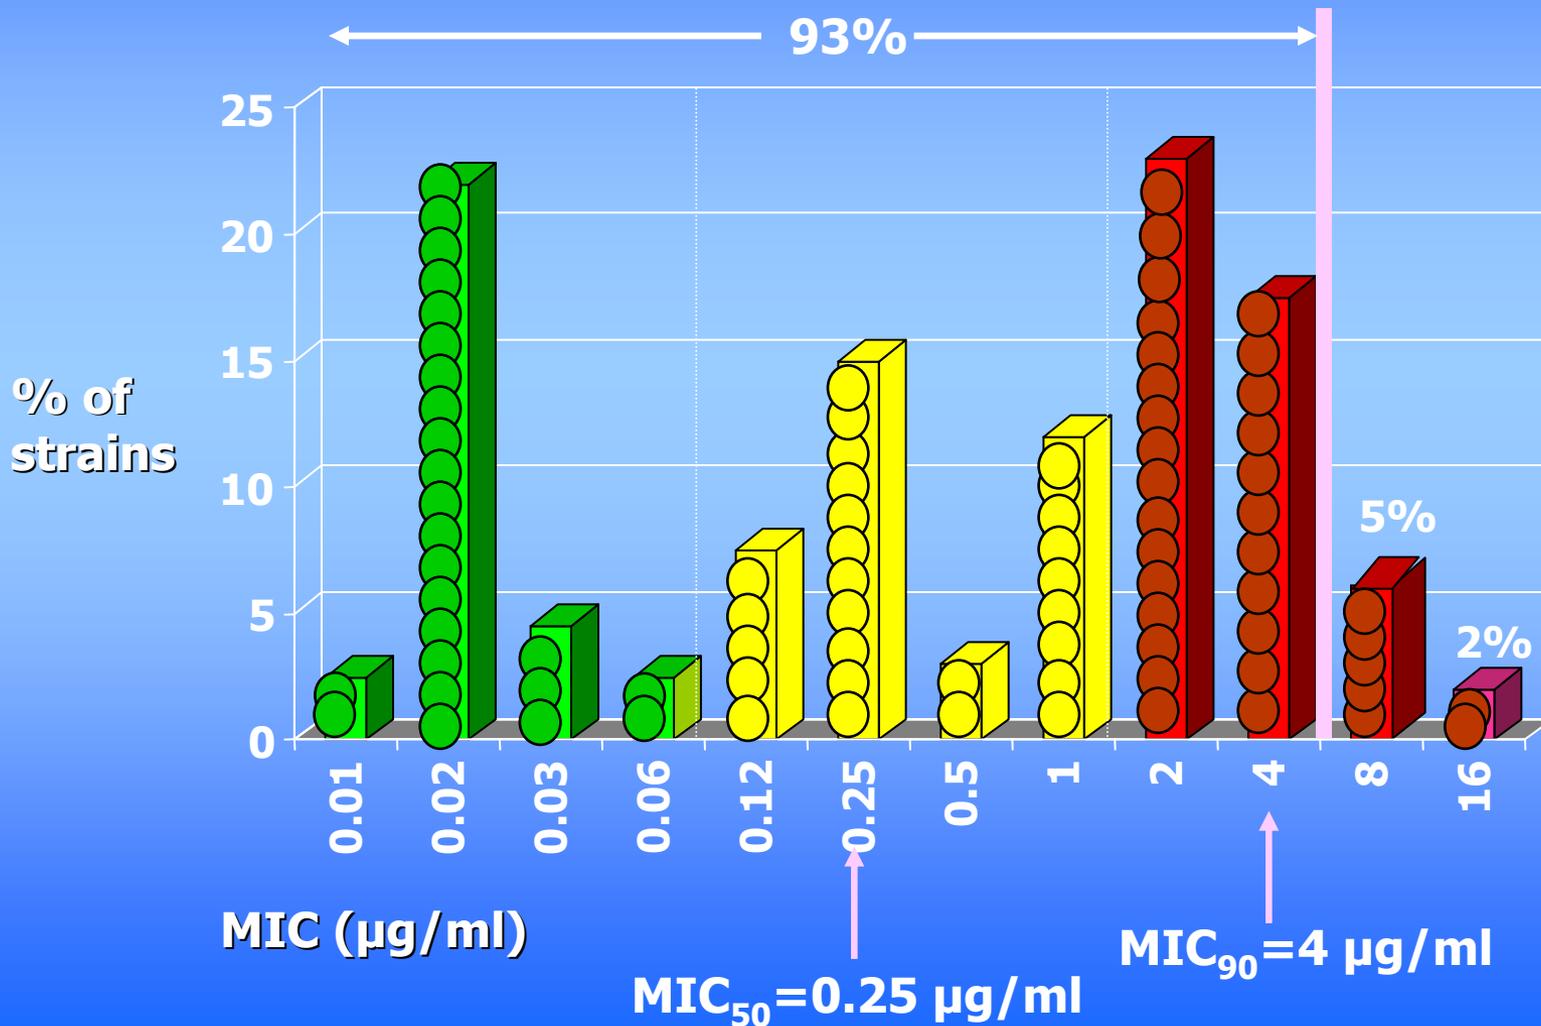

Minimal inhibitory concentration

The more "potent" the antibiotic, the less is needed to kill the bacteria, and the MIC is LOWER

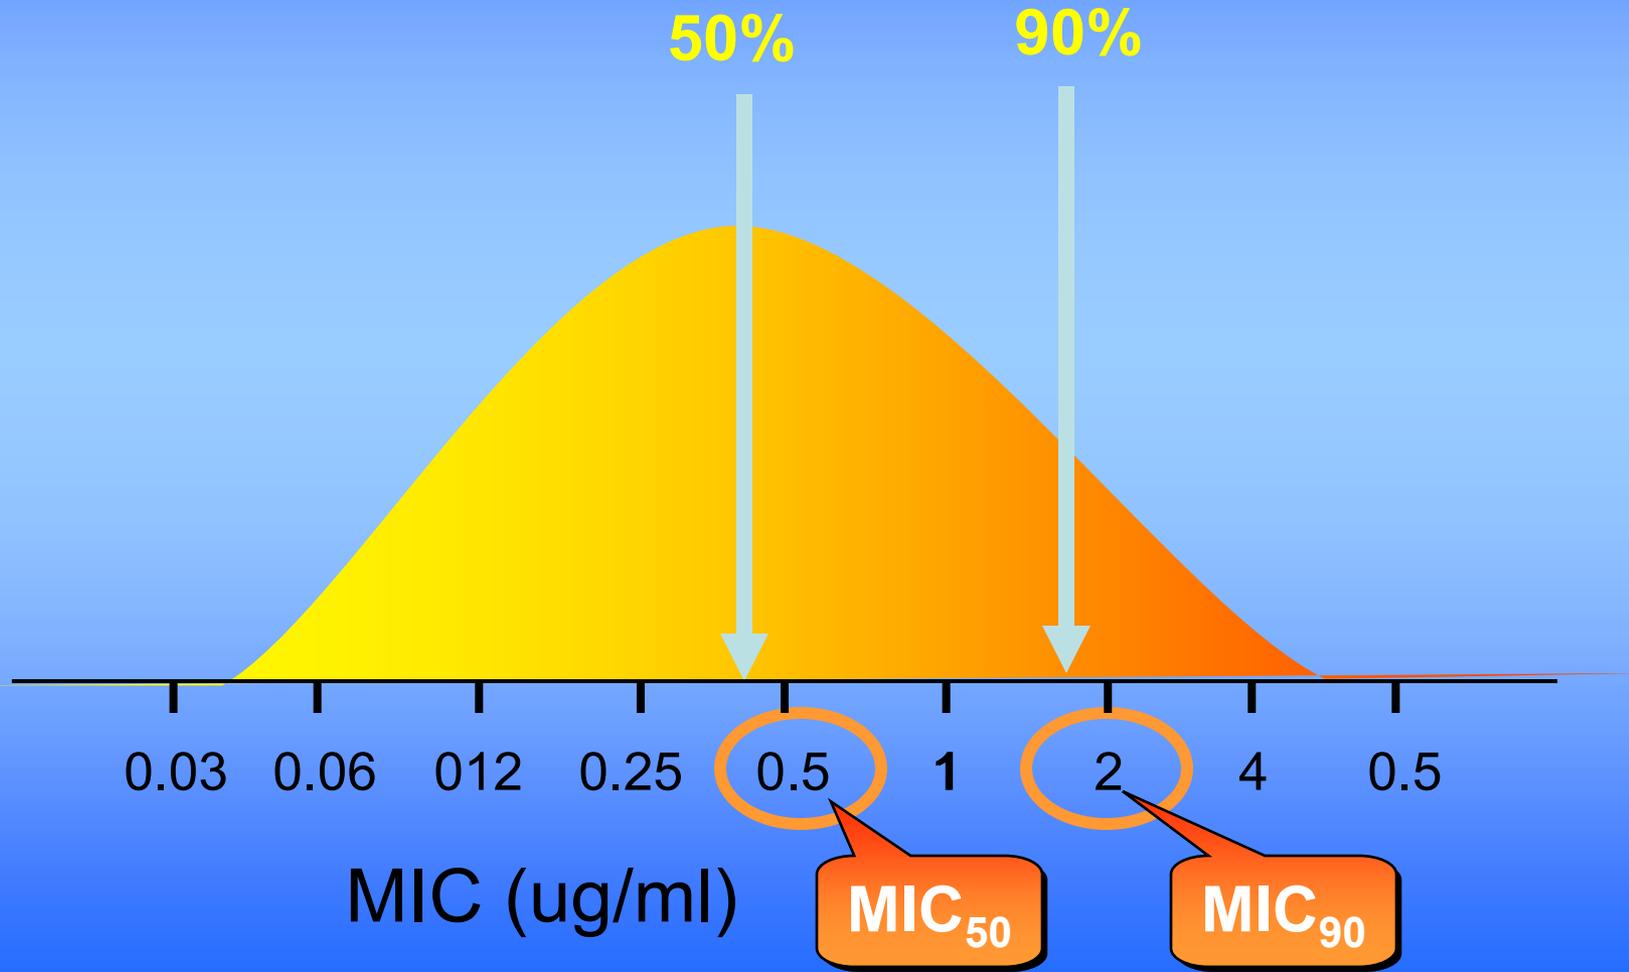

Increasing antibiotic concentration

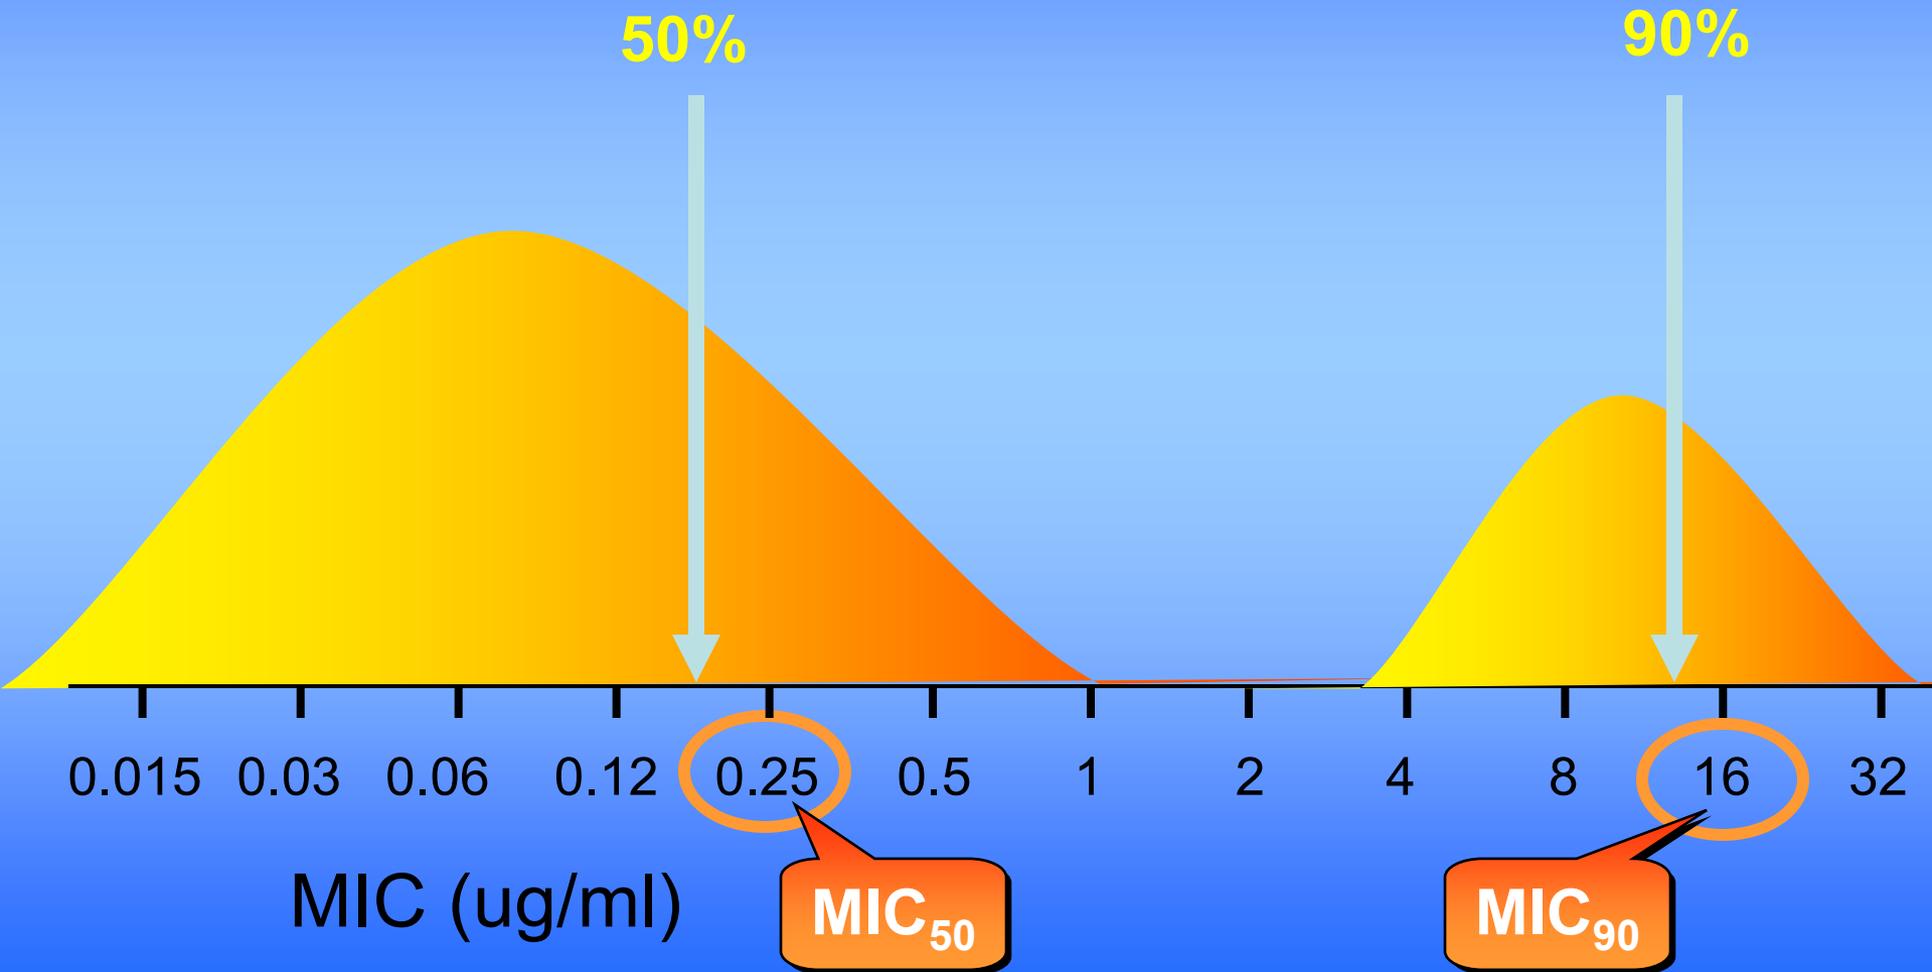

MIC₉₀: the lowest concentration that includes at least 90% of the strains tested

MIC₅₀ and MIC₉₀ unimodal population

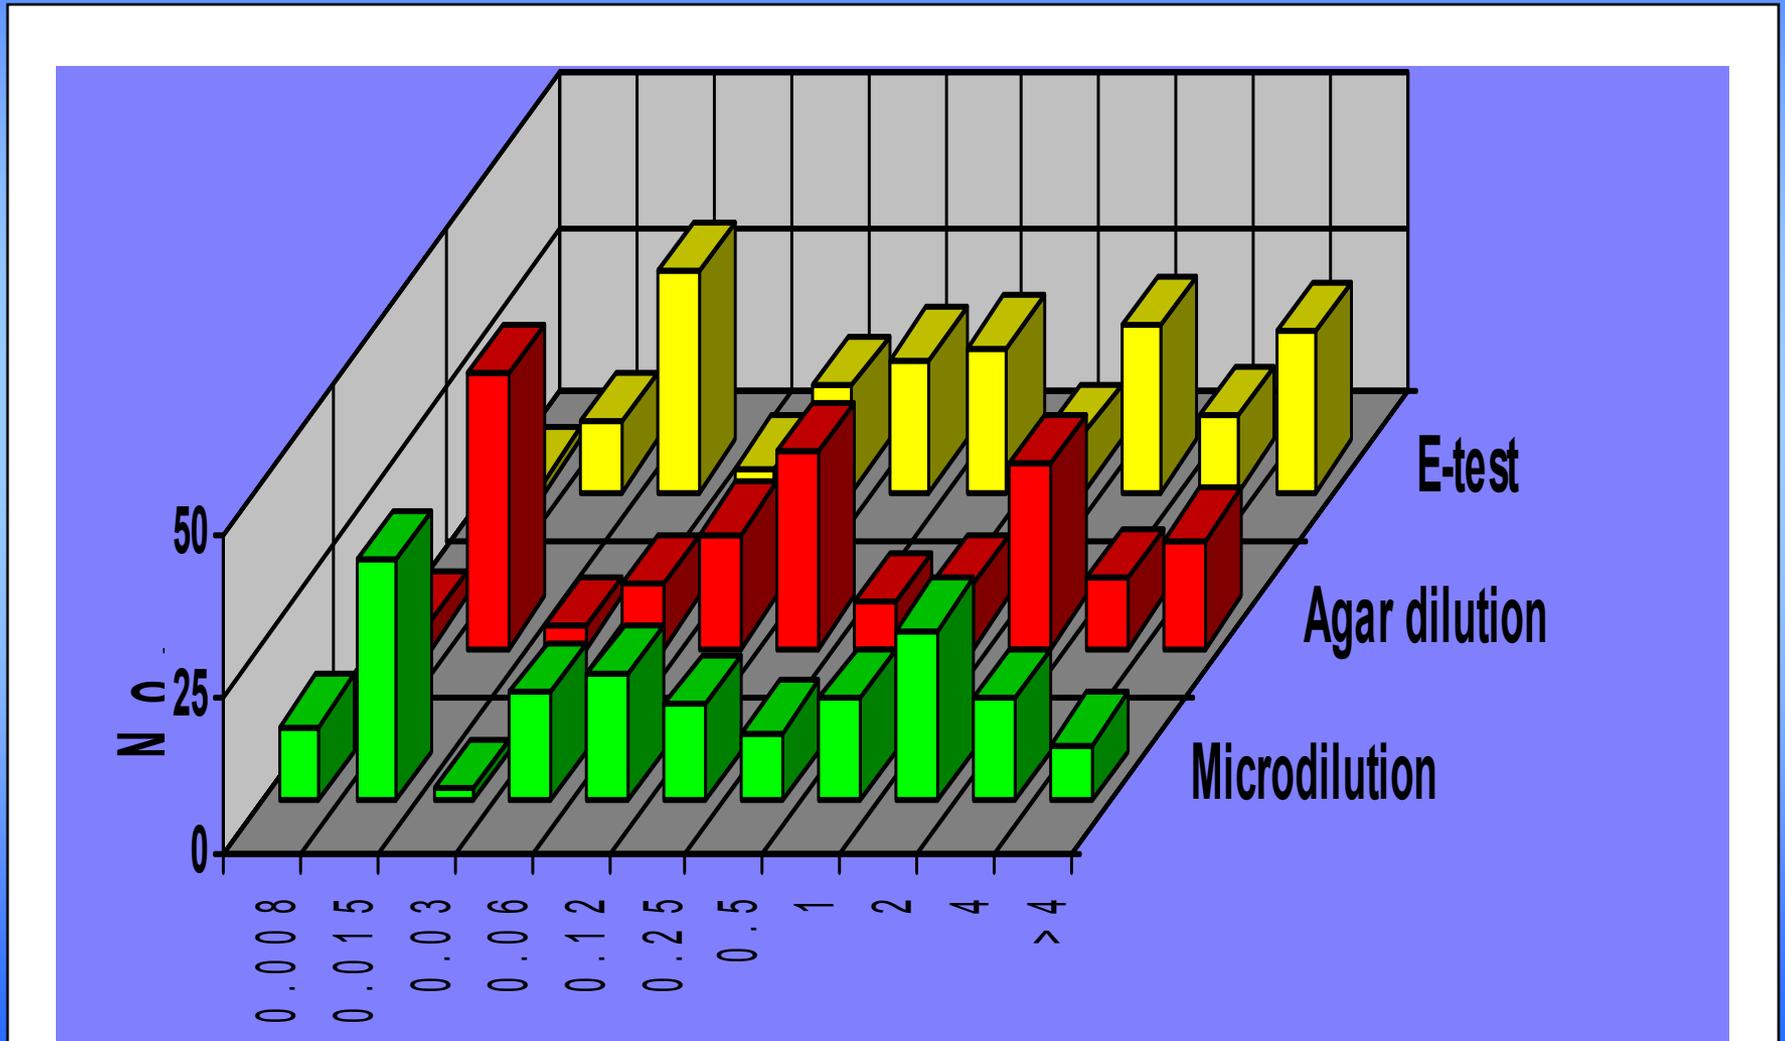

MIC₅₀ and MIC₉₀ bimodal population

Streptococcus pneumoniae

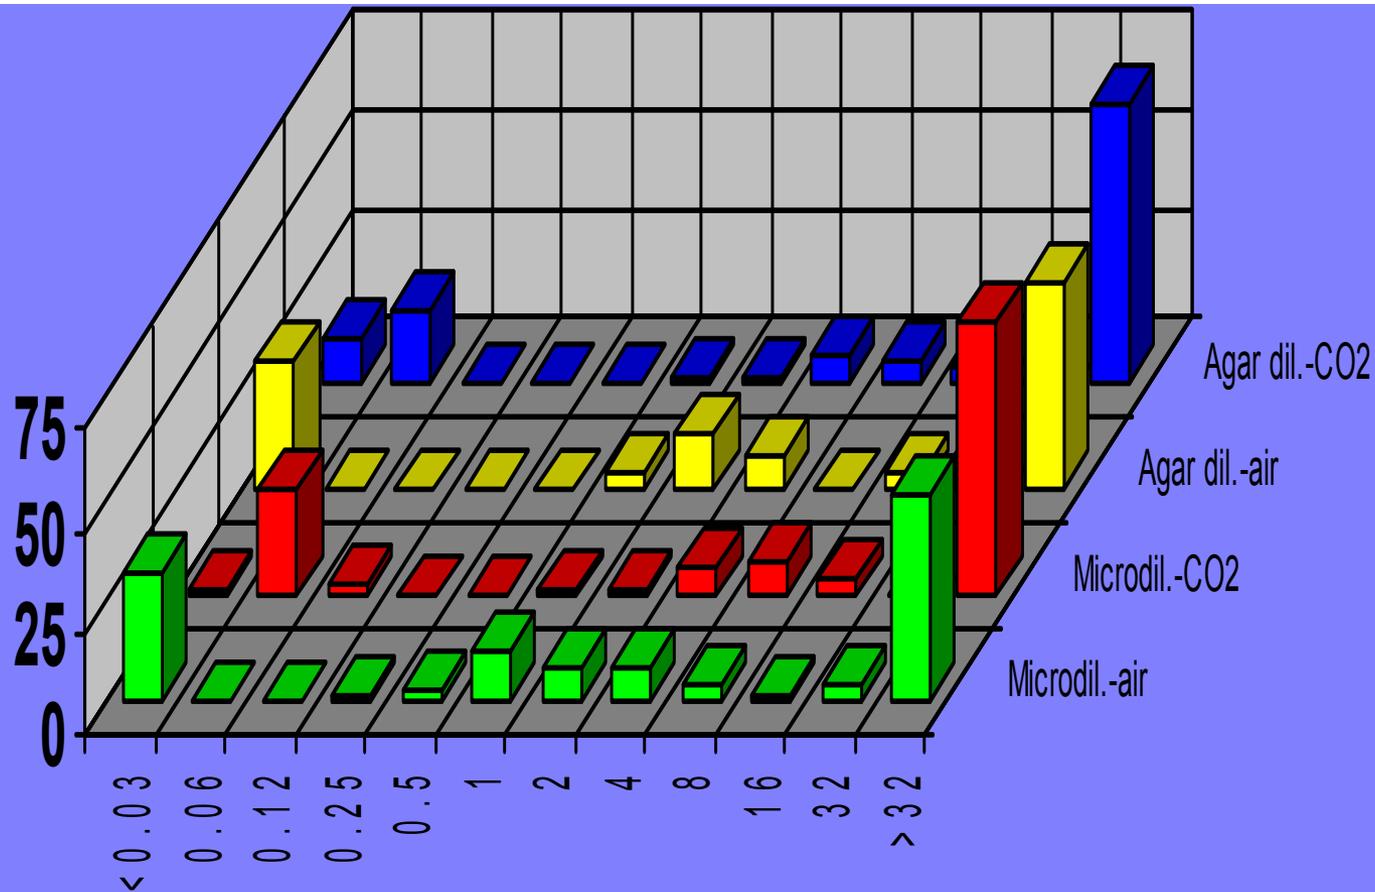

Penicillin MIC variation by method

From Jacobs et al., J. Clin. Micro. 1998, 36:179

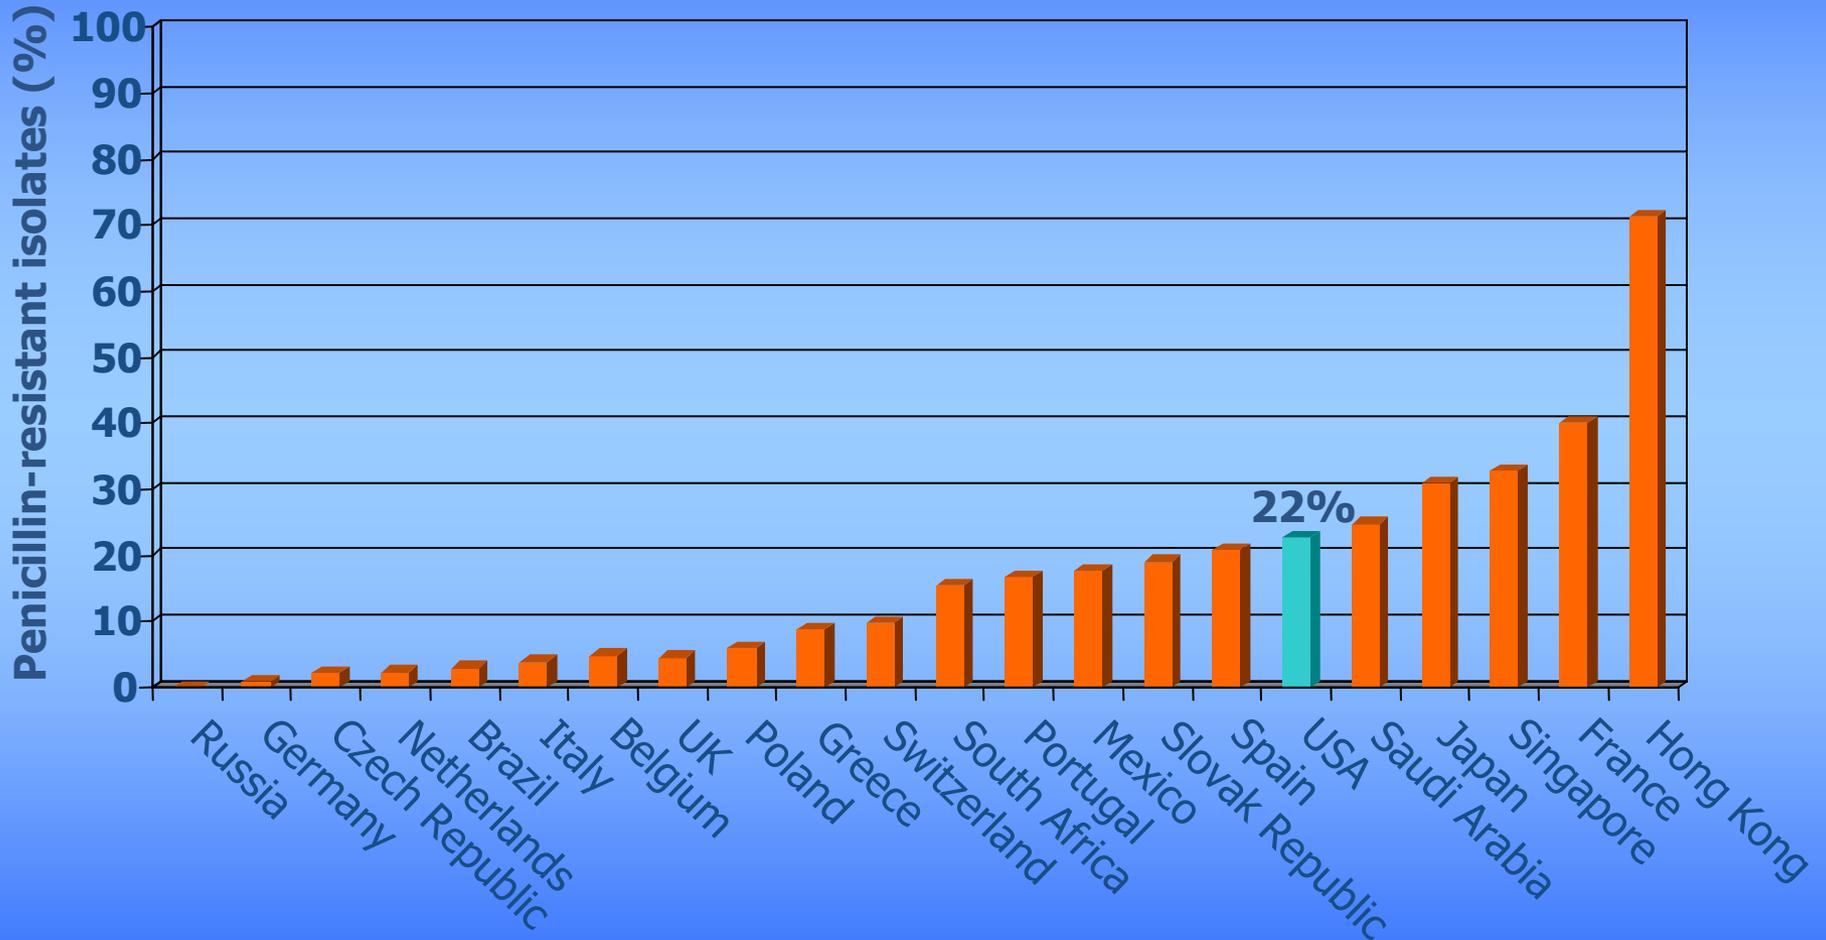

Streptococcus pneumoniae

Erythromycin MIC variation by method

From Fasola et al., Antimicrob. Agents Chemother. 1997, 41:129-134

S. pneumoniae Pen-R: The Alexander Project 2000

Penicillin-resistant defined as penicillin MIC ≥ 2 $\mu\text{g/mL}$

Subinhibitory effects of antibiotics

Postantibiotic effect; PAE in vitro

Definition:

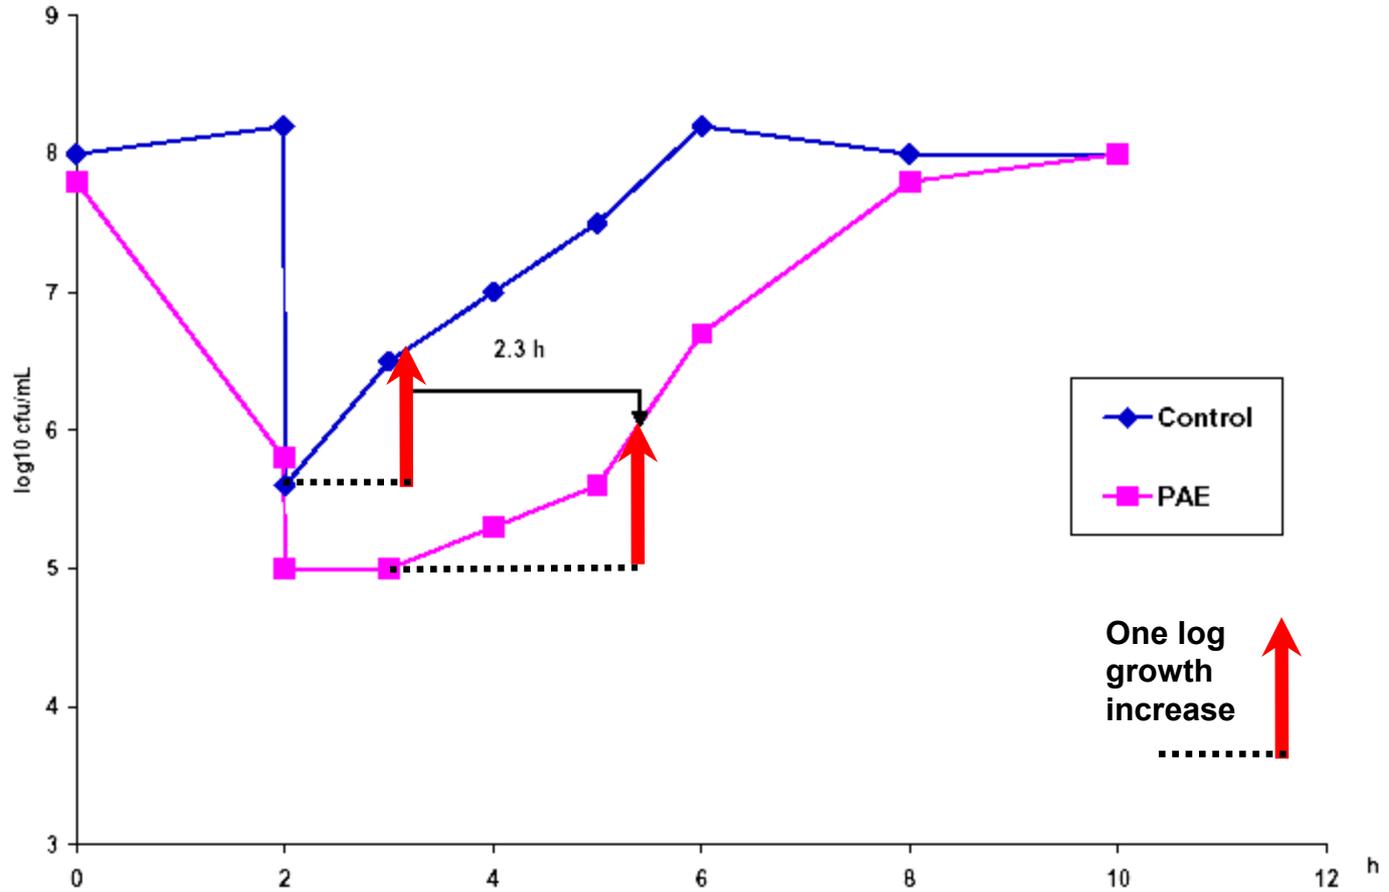

- Suppression of bacterial growth after short exposure of organisms to antibiotics

$$PAE = T - C$$

T= The time required for the exposed culture to increase one \log_{10} above the count observed immediately after drug removal

C= The corresponding time for the unexposed control

Postantibiotic effect

Odenholt et al. SJID, 1988

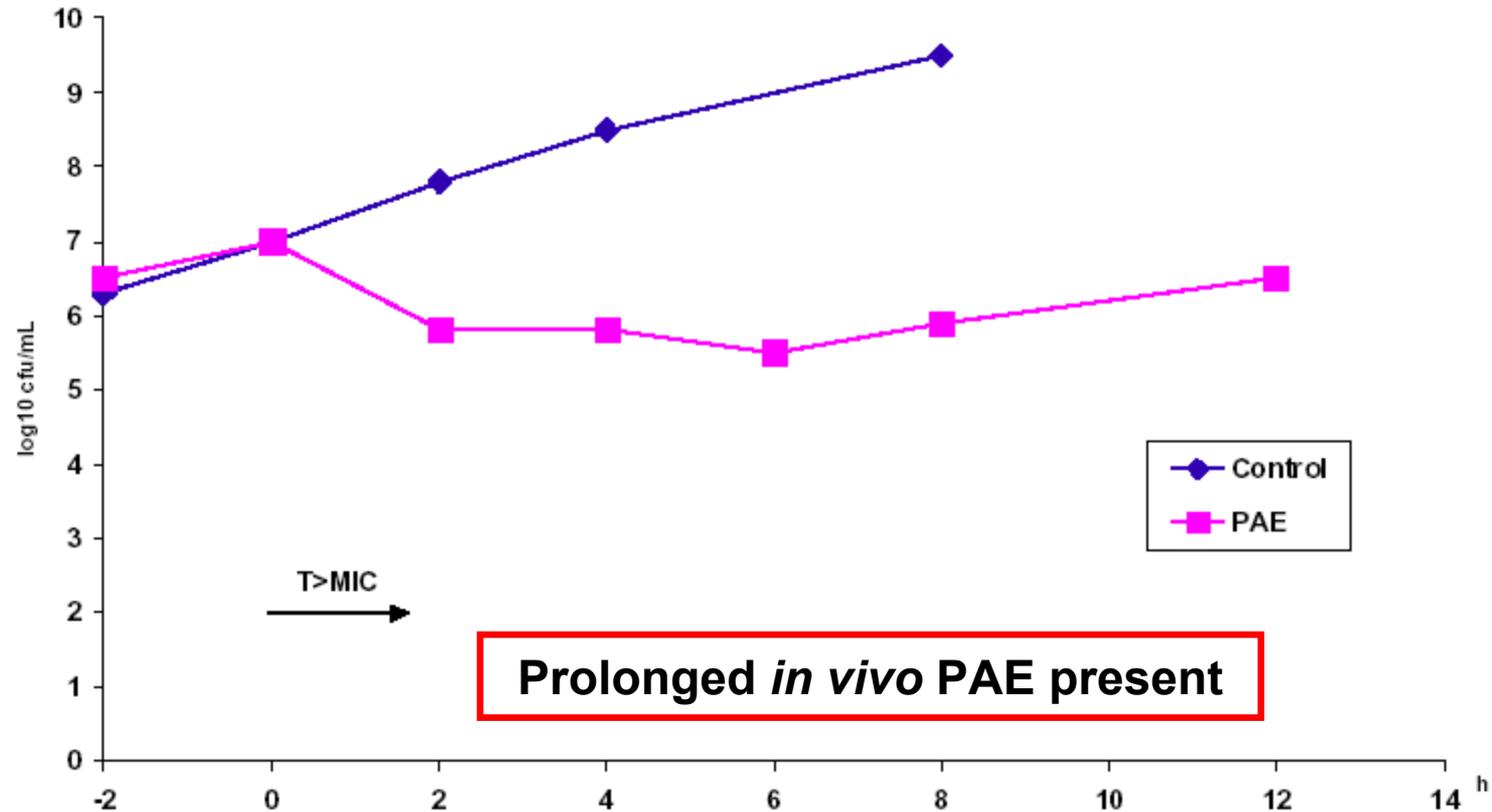

Postantibiotic effect in vivo

Definition

$$PAE = T - C - M$$

- T = the time required for the counts of cfu in thighs of treated mice to increase one \log_{10} above the count closest to but not less than the time M
- C = the time required for the counts of cfu in thighs of untreated mice to increase one \log_{10} above the count at time zero
- M = the time serum concentration exceeds the MIC

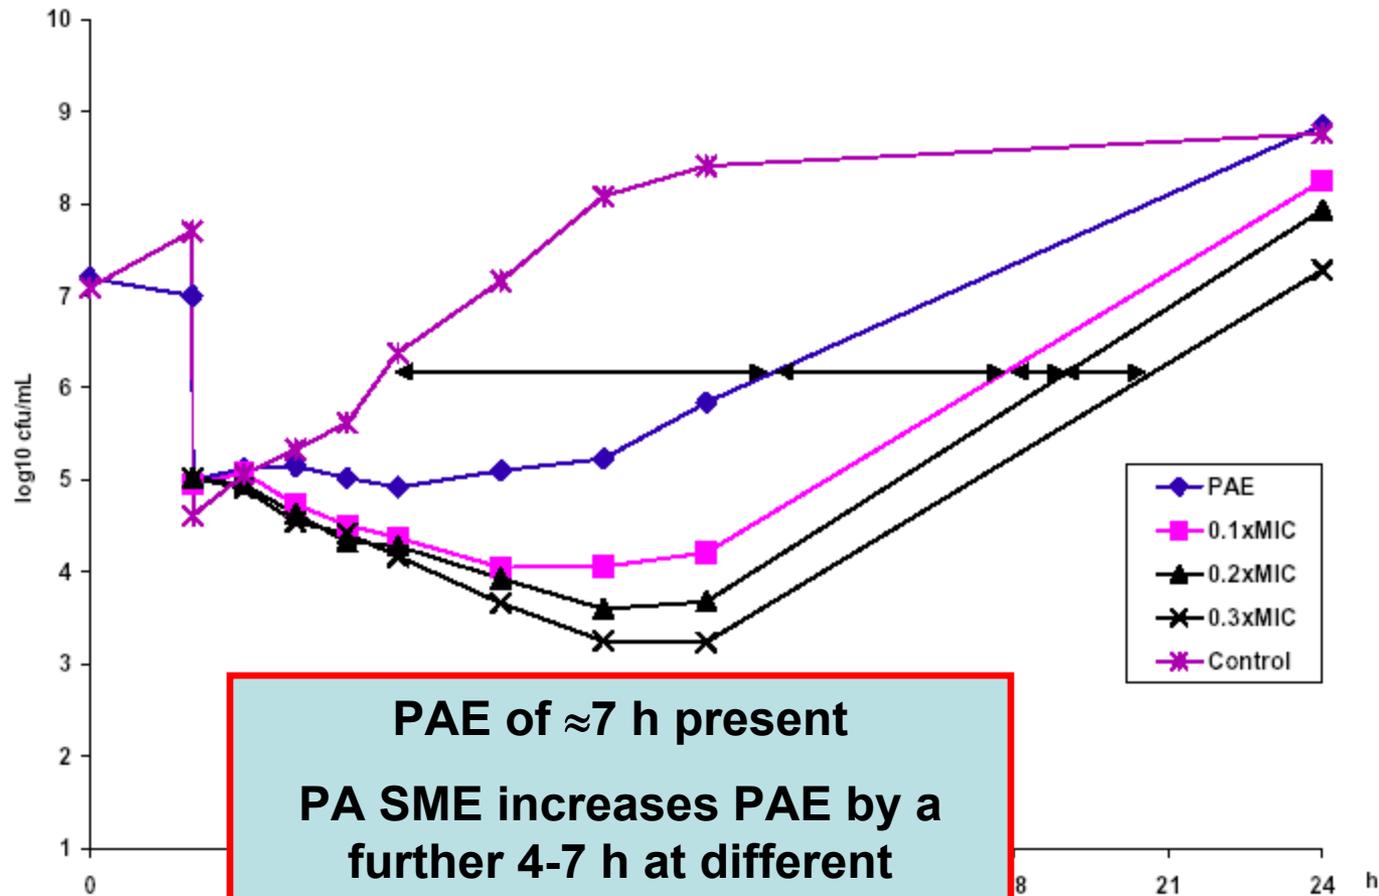

The postantibiotic effect of gentamicin against *K. pneumoniae* in vivo

Prolonged *in vivo* PAE present

Fantin et al. JAC, 1990

PA SME of telithromycin against *H. influenzae*

PAE of ≈ 7 h present
PA SME increases PAE by a further 4-7 h at different subinhibitory drug concentrations

Subinhibitory effects of antibiotics

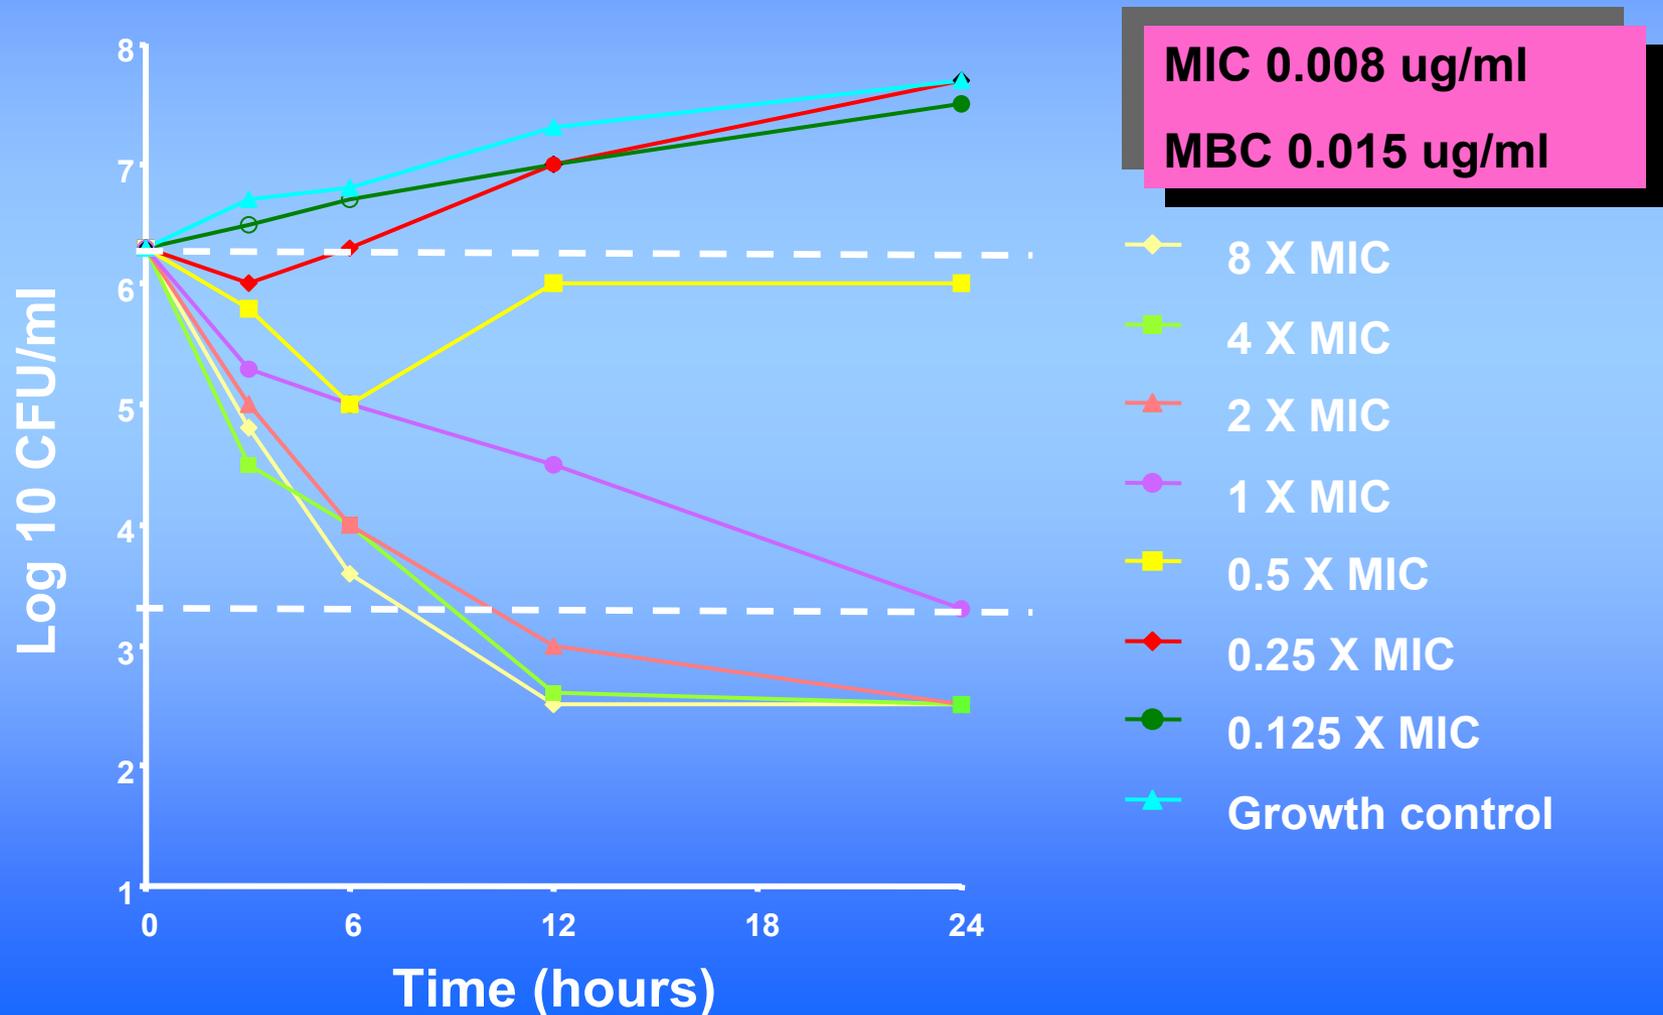

Subinhibitory effects such as PAE and PAE-SME can often be demonstrated and may account in part for concentration-dependent PK/PD interactions in vivo

Bactericidal activity

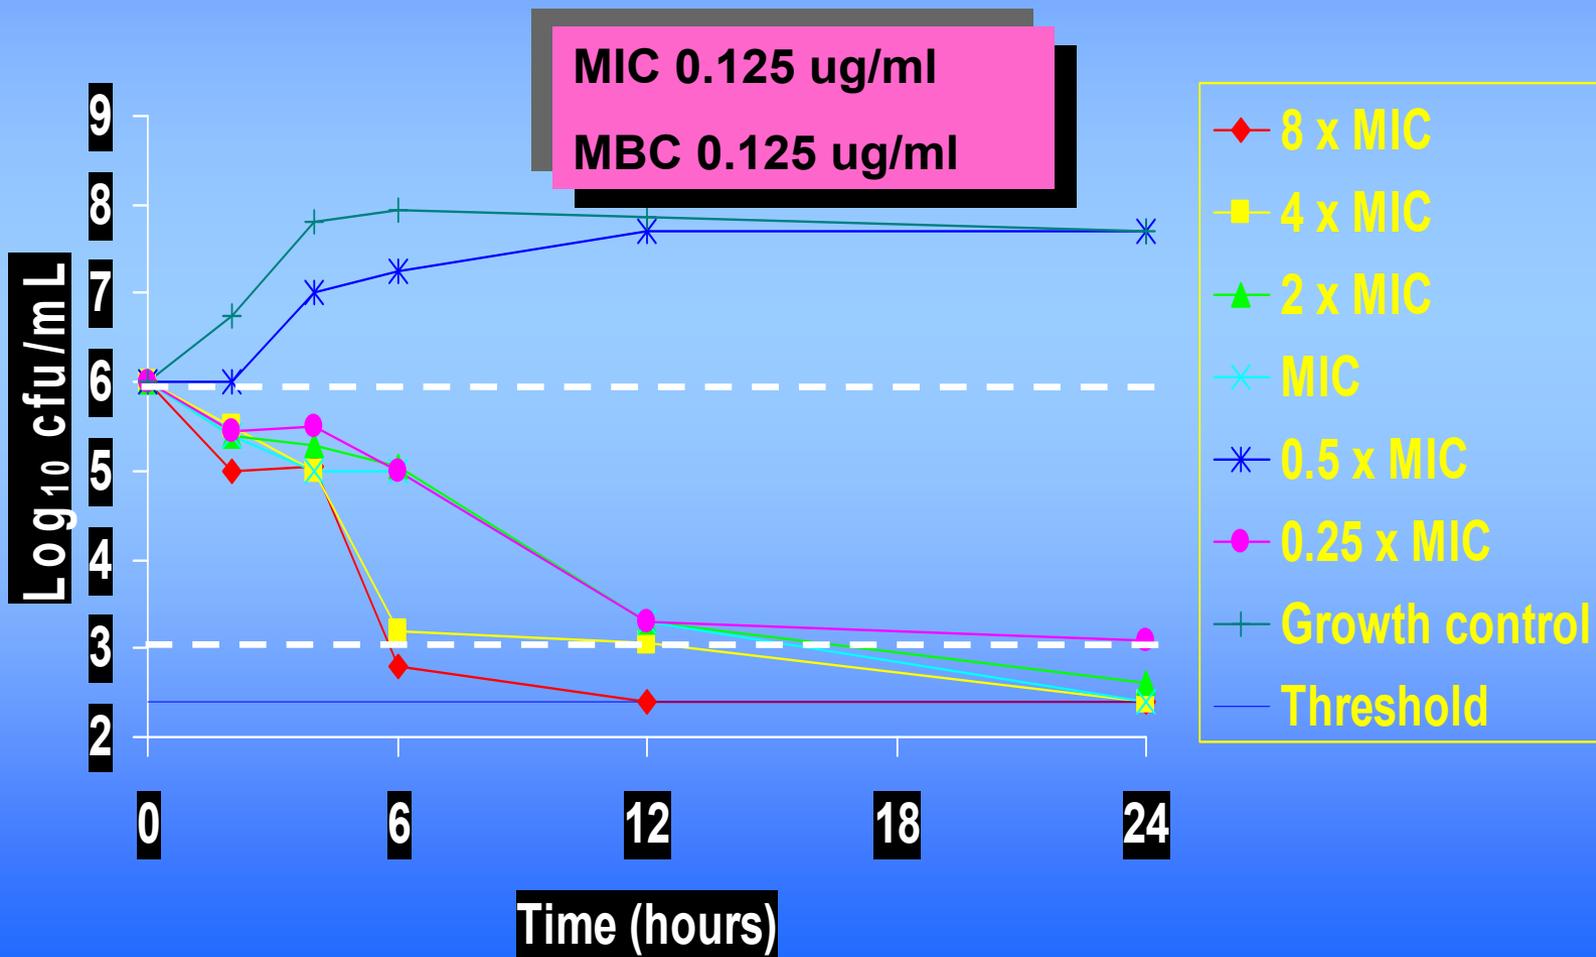

Bactericidal activity: Time-kill determination

- **MICs do not provide data on whether the isolate has only been inhibited or has been “killed”**
- **MBCs provide data on bacterial killing (defined as a 3 log₁₀ kill in 24 h)**
- **Time-kill curves provide more detailed data on extent and time course of killing**

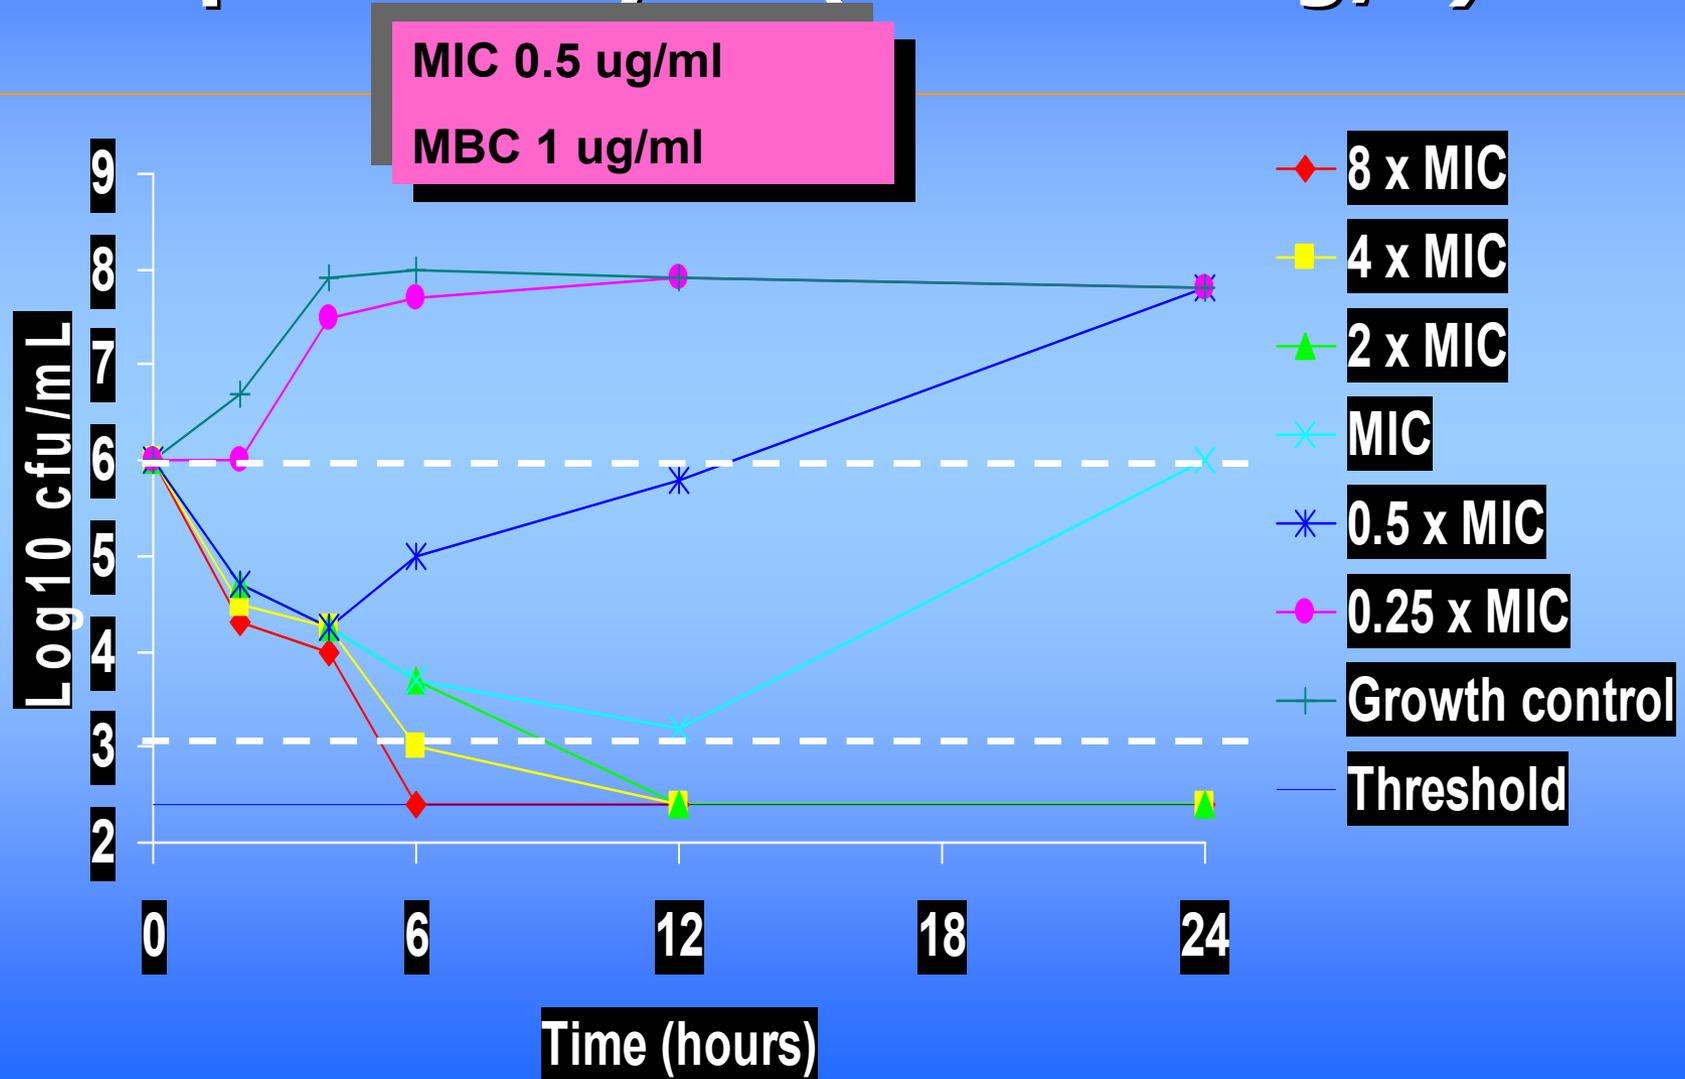

Gemifloxacin time kill of a penicillin resistant strain of *S.pneumoniae* (gemifloxacin MIC 0.016 ug/ml)

Time Kill of *S. pneumoniae* for telithromycin (MIC 0.125 mg/L)

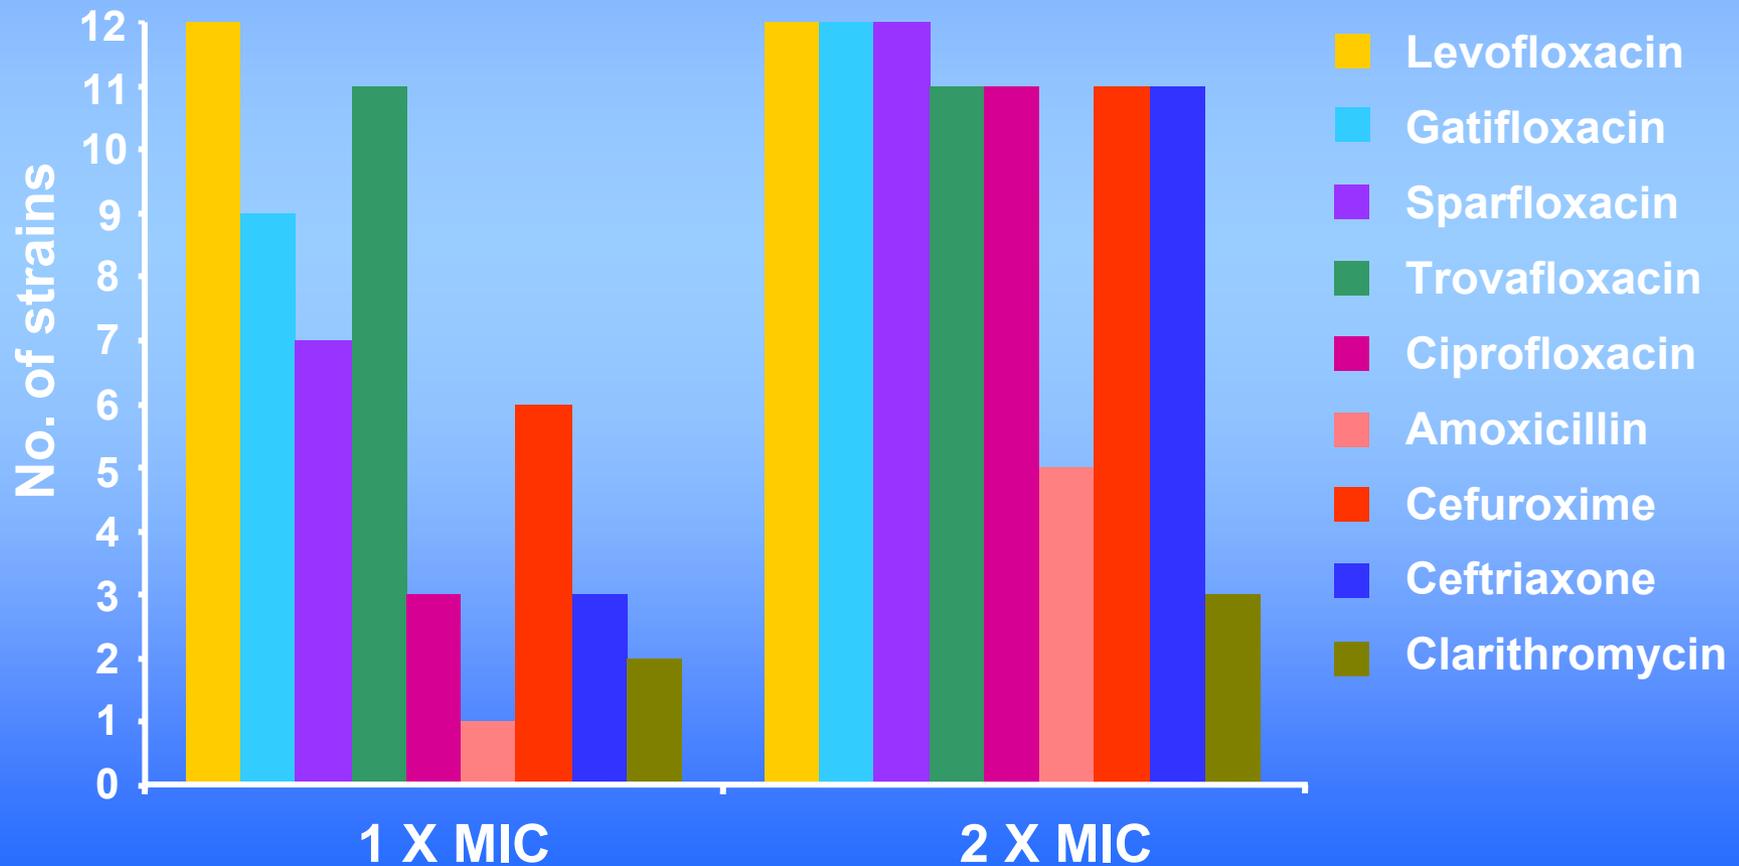

Time Kill of *S. pneumoniae* for pristinomycin (MIC 0.5 mg/L)

Time kill of *S.pneumoniae*

3 log₁₀ kill in 24 hours

Bactericidal activity against most strains at MICs for quinolones compared to at 2X MICs for beta-lactams

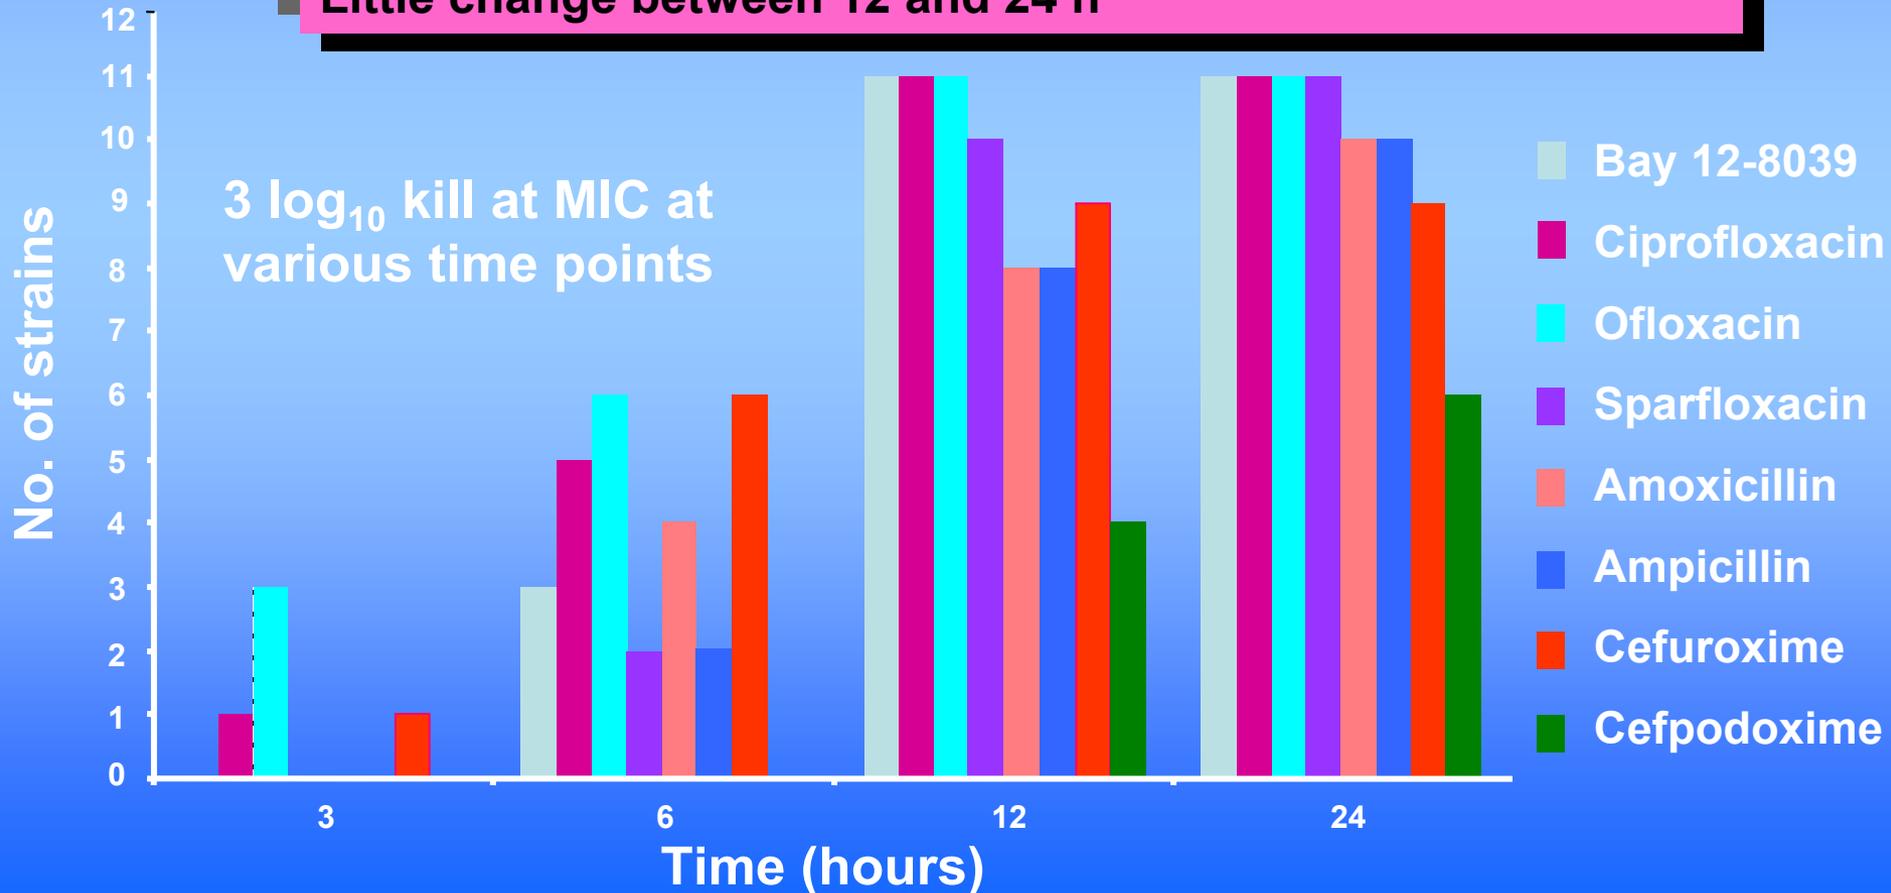

Time kill of *S.pneumoniae*

Little bactericidal activity at MIC at 3 h

Bactericidal activity against up to half of the strains at 6 h

Bactericidal activity against most strains at 12 h, with faster killing by quinolones than by beta-lactams

Little change between 12 and 24 h

MIC distributions of RTI pathogens

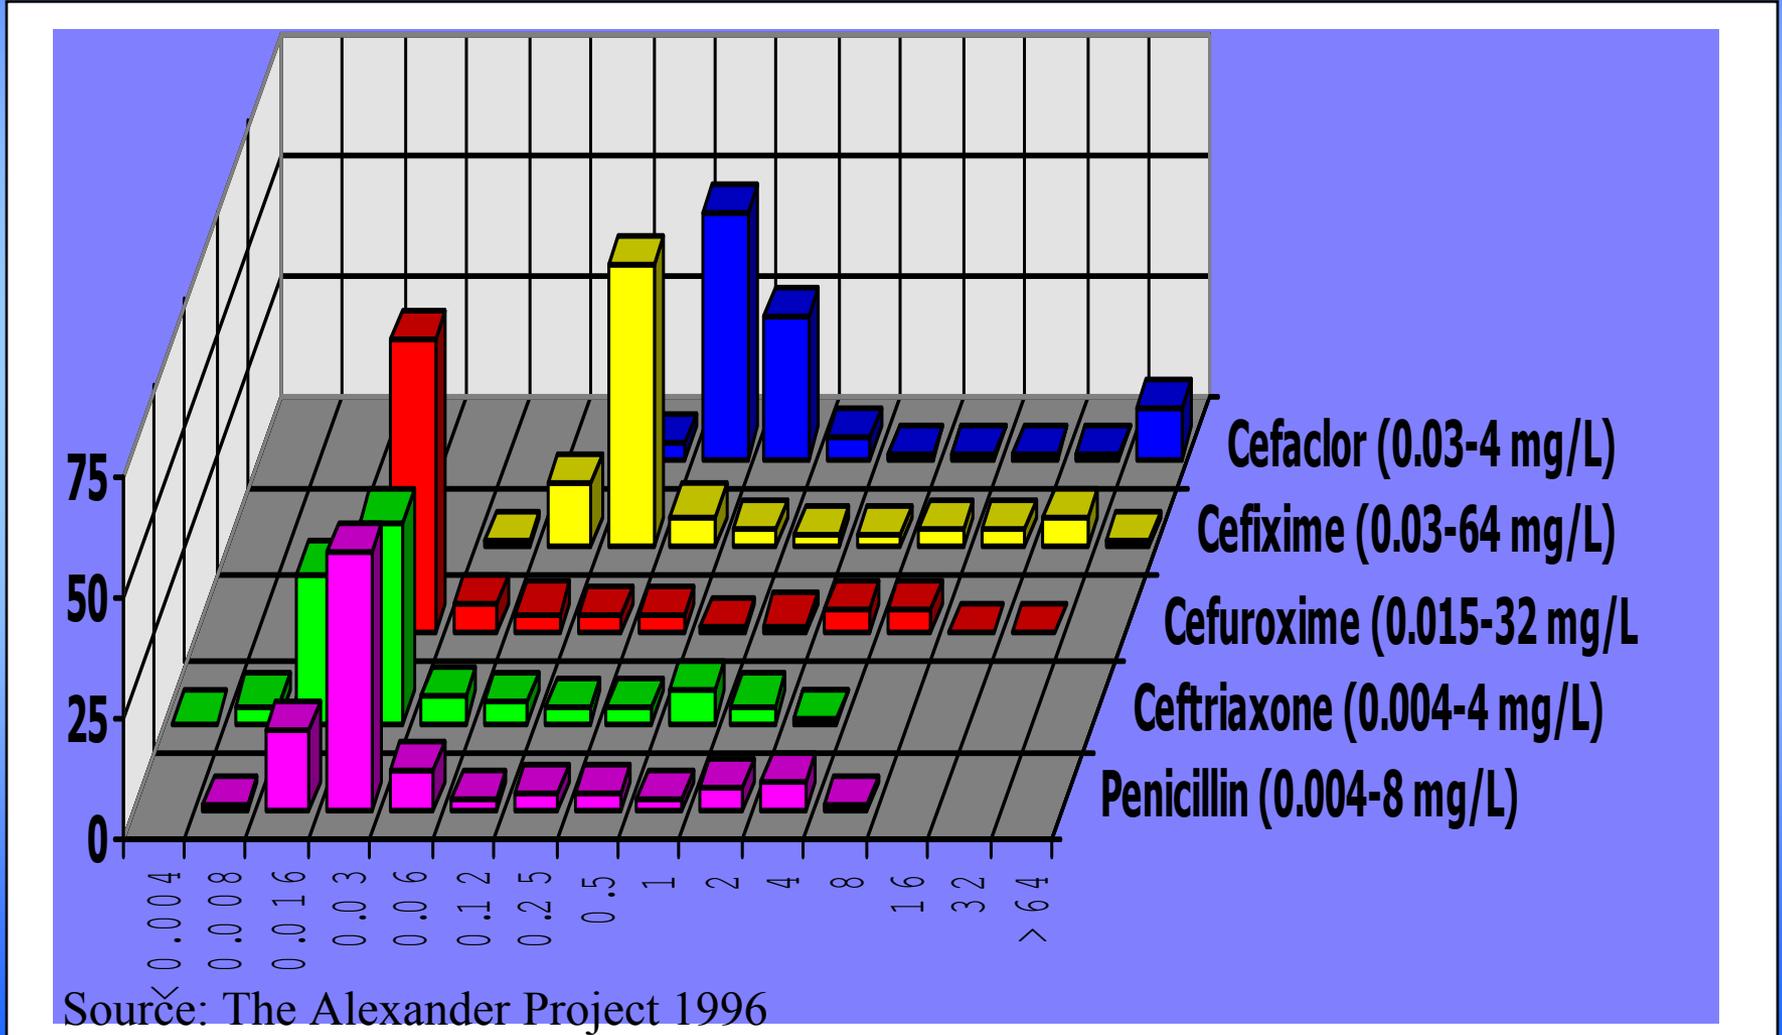

MIC distributions of RTI pathogens

- **Can MIC distributions provide a basis for comparing susceptibilities of different bacterial species causing infections at the same sites?**
- **Can MIC distributions show if discrimination between isolates with different MICs is likely to be possible in clinical studies?**
- **Can MIC distributions be applied to clinically determined breakpoints to determine susceptibility of isolates?**

MIC distributions
