Our main research interests...

antibiotics: from molecules to man

What will it be all about?

- The antibiotic crisis ...
 - are antibiotics following a path of madness?
 (the reality in hospitals and in the community...)
 - the "resistome" (or why do we will always have resistance...)
 - the "selectome" (or why do we favor emergence of resistance)
- The main lines of action (for research)
 - > the 7 pillars of wisdom?
- Laboratory and translational studies at LDRI (examples)
 - poorly exploited targets (D-Ala-D-Ala ligase)
 - refurbishing old antibiotics (aminogycosides, polymyxins, temocillin)
 - better antibiotic use (PK/PD, intracellular bacteria)
 - PK/PD approaches to mitigate the emergence of resistance (β-lactams and fluoroquinolones)

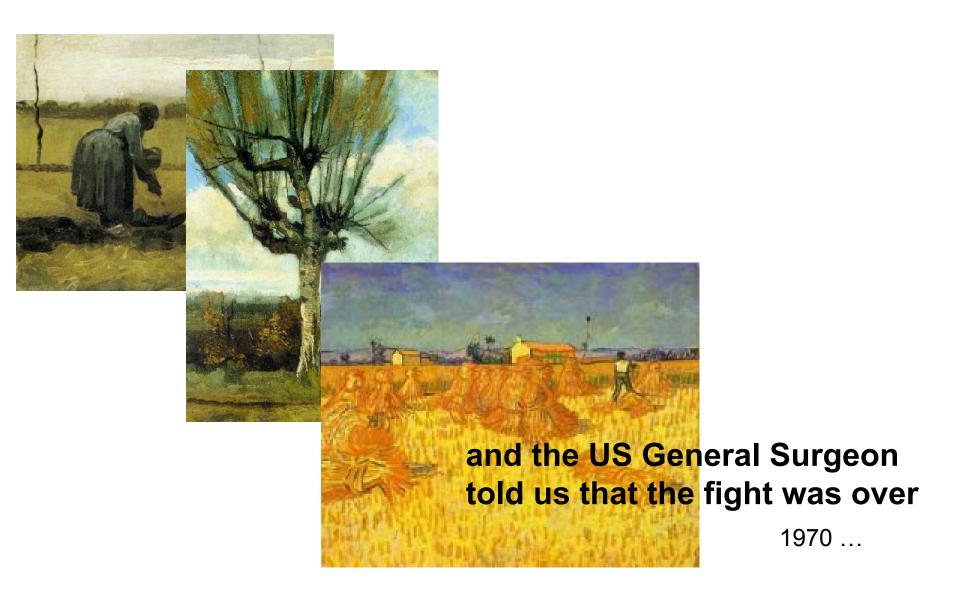

discovery in soil bacteria and fungi

1928 - ...

1950 – 1980 ...

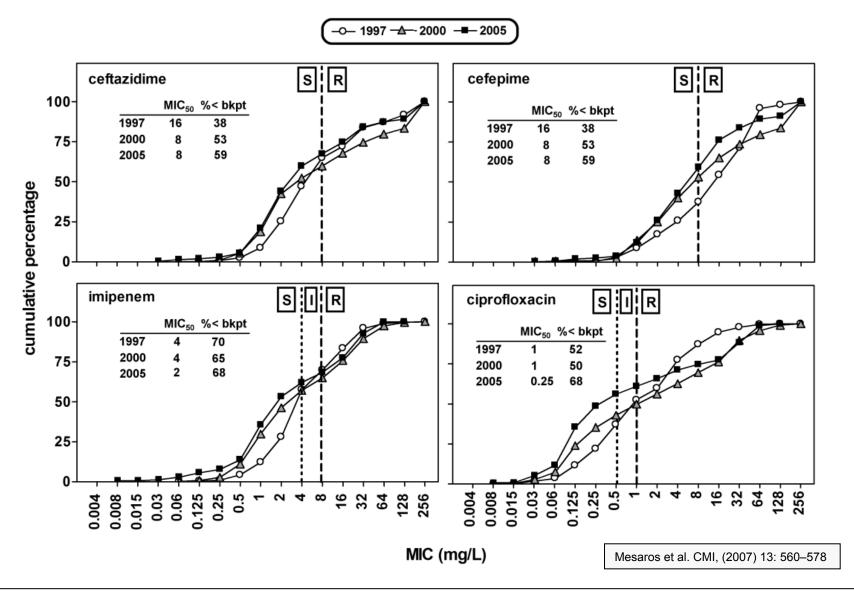

and then we all saw the blooming tree of semi-synthetic and totally synthetic antibiotics

2012 ...

Resistance of *P. aeruginosa in hospitals* (International data – EUCAST breakpoints)

Spreading of NDM-1 in the community ...

NDM-1-Producing *Klebsiella pneumoniae* Resistant to Colistin in a French Community Patient without History of Foreign Travel

Corinne Arpin, ^a Patrick Noury, ^b Delphine Boraud, ^b Laure Coulange, ^a Alain Manetti, ^c Catherine André, ^a Fatima M'Zali, ^a and Claudine Quentin ^a

Université de Bordeaux, Microbiologie Fondamentale et Pathogénicité UMR 5234, Bordeaux, France^a; Laboratoire de Biologie Médicale EXALAB, Site de Villenave d'Ornon, Villenave d'Ornon, France^b; and Agence Régionale de Santé, Espace Rodesse, Bordeaux, ^c France

A carbapenem-resistant Klebsiella pneumoniae strain, Kp5196, was responsible for an uncomplicated cystitis in a patient living at home and without history of foreign travel. This isolate produced the metallocarbapenemase NDM-1 and was resistant to all antibiotics except tetracyclines and colistin. The K. pneumoniae strain belonged to sequence type ST15, and $bla_{\text{NDM-1}}$ was carried by a nontypeable conjugative plasmid. Two months later, a similar ST15 isolate, Kp5241, was present in the patient but was additionally colistin resistant.

The resistome ...

The antibiotic resistome.

- all the genes and their products that contribute to antibiotic resistance.
- highly redundant and interlocked system
- clinical resistance under represents the resistance capacity of bacteria.
- existing biochemical mechanisms (protoresistome) serve as a deep reservoir of precursors that can be coopted and evolved to

Antibiotic Resistance:Implications for Global Health and Novel Intervention Strategies: Workshop Summary http://www.nap.edu/openbook.php?record id=12925

Clinical resistance: the tip of the iceberg?

- "Clinical" resistance genes are found on pathogenic bacteria.

 These are the fewest but also the most problematic ones at present.
- "Father resistance genes" found on antibiotic producers.
 (microorganisms that naturally produce antibiotics have their own protection mechanisms to avoid the adverse effects of the antibiotics on themselves).
 - ➤ These genes are a strong source for the pathogenic bacteria.
- Cryptic resistance genes.
 (genes are embedded in the bacterial chromosome that may be overexpressed when "needed")
- Precursor genes.
 (encode proteins with basal level activity against antibiotics but may evolve to a "full resistance genes" given the appropriate selection pressure.

The hidden risk of therapy (in our hospitals ...)

"Father resistance genes": an original example with aminoglycosides

Proc. Nat. Acad. Sci. USA Vol. 70, No. 8, pp. 2276-2280, August 1973

Aminoglycoside Antibiotic-Inactivating Enzymes in Actinomycetes Similar to Those Present in Clinical Isolates of Antibiotic-Resistant Bacteria

(streptomyces/origin of R-factors/gentamicin-acetate)

RAOUL BENVENISTE* AND JULIAN DAVIES†

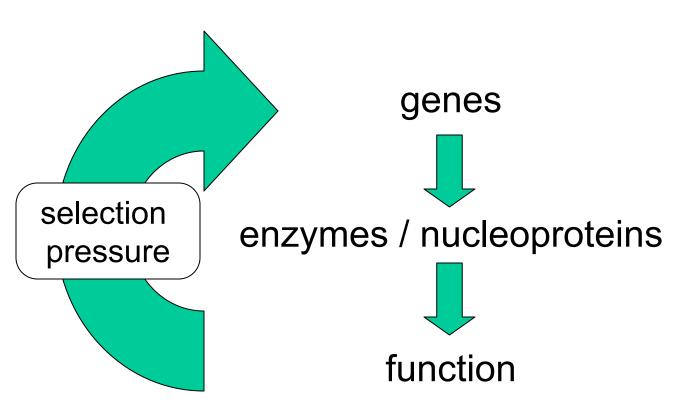

Department of Biochemistry, College of Agricultural and Life Sciences, University of Wisconsin—Madison, Madison, Wis. 53706

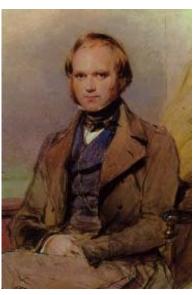

Communicated by Henry Lardy, May 11, 1973

One of the most striking properties of the actinomycetes is the extent to which they produce antibiotics; most of the aminoglycoside antibiotics (streptomycin, neomycin, kanamycin, gentamicin, tobramycin, and lividomycin) are produced by them.

The selectome

A simple application of Darwin's principles ...

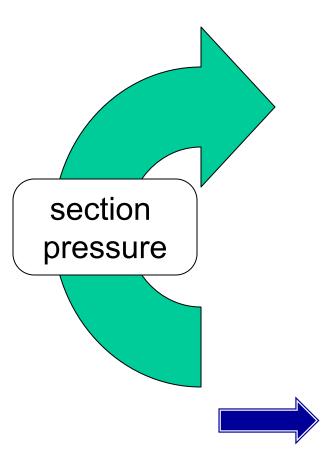

Detail of watercolor by George Richmond, 1840. Darwin Museum at Down House

How and why can you select so easily?

A simple application of Darwin's principle... to a highly plastic material...

- an infectious focus typicaly contains more than 10⁶ - 10⁹ organisms
- most bacteria multiply VERY quickly (20 min...) and do mistake ...
- they are not innocent or useless mistakes

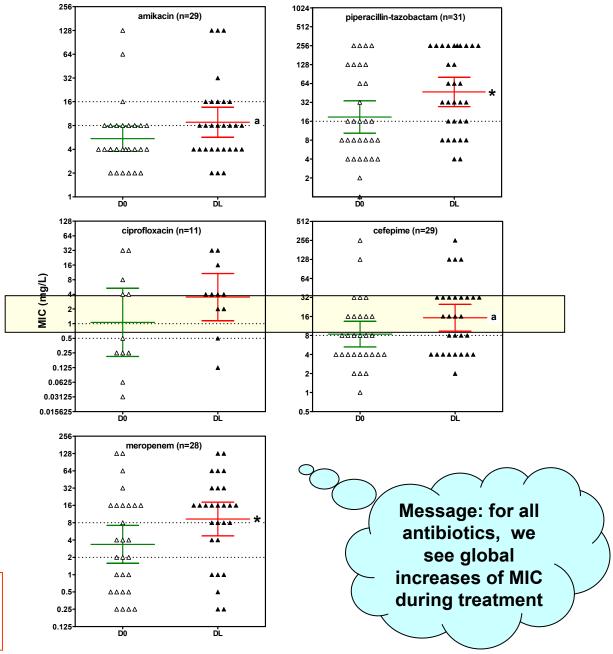

fast selection of the fitest!

Do you remain effective while treating?

- D0: initial isolate
 DL: last isolate obtained
- individual values with geometric mean (95 % CI)
- S (lowest line) and R (highest line) EUCAST breakpoints
- * p < 0.05 by paired t-test (twotailed) and Wilcoxon nonparametric test
- ^a p < 0.05 by Wilcoxon nonparametric test only

Note: stratification by time between D0 and DL gave no clue (too low numbers)

Actually, selecting for resistance is easy even in a closed system...

Novel aminoglycosides *

Advantages

- wide spectrum and highly bactericidal
- no metabolism and linear pharmacokinetics
- extensive knowledge of their therapeutic and toxicological properties (leading to simple "once-daily dosing")

Challenges

- extensive development of resistance (mostly enzyme-mediated
 aminoglycoside-modifying enzymes [AME])
- nephrotoxicity and ototoxicity remain of concern and seem linked to activity

^{*} using proprietary data of Achaogen Inc., South San Francisco, Cal. and example of collaborative approach

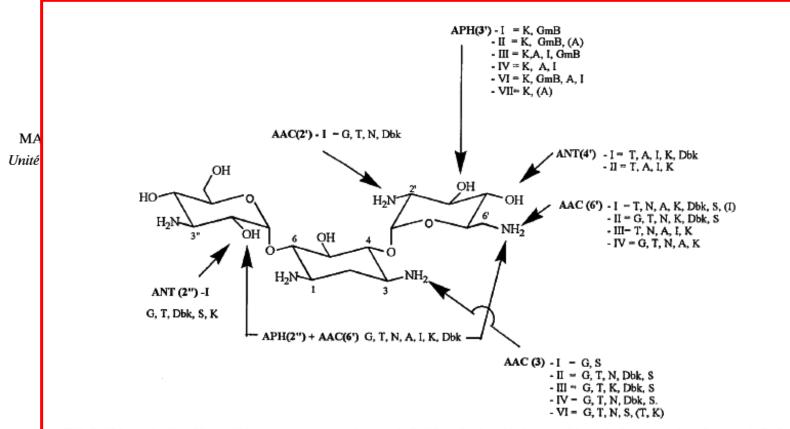

FIG. 3. Major aminoglycoside-modifying enzymes acting on kanamycin B (this aminoglycoside is susceptible to the largest number of enzymes). Each group of enzymes inactivates specific sites, but each of these sites can be acted upon by distinct isoenzymes (roman numerals) with different substrate specificities (phenotypic classification; each phenotype comprises several distinct gene products [denoted by lowercase letters after the roman numeral in the text]); at least one enzyme is bifunctional and affects both positions 2" (O-phosphorylation) and 6' (N-acetylation)). The main clinically used aminoglycosides on which these enzymes act are as follows: amikacin (A), dibekacin (Dbk), commercial gentamicin (G) (see text), gentamicin B (GmB), kanamycin A (K), isepamicin (I), netilmicin (N), sisomicin (S), and tobramycin (T) (see text for discussion of arbekacin, sagamicin, and dactimicin). The drug abbreviations which appear in parentheses are those for which resistance was detectable in vitro even though clinical resistance was not conferred. Based on the data of Shaw et al. (89).

Vol. 43, No. 5

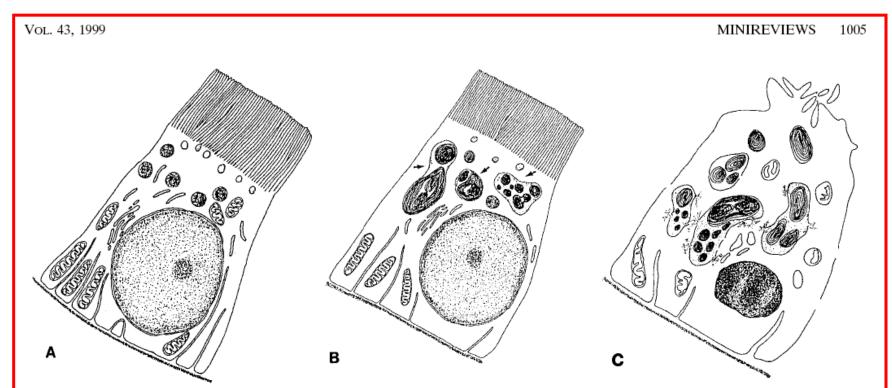

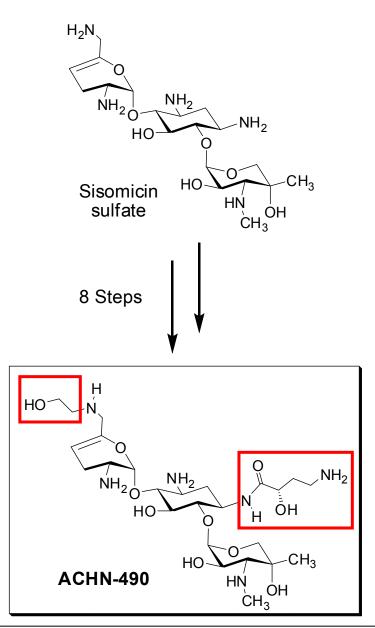

FIG. 1. Ultrastructural alterations induced in proximal tubular cells during aminoglycoside treatment. (A) Control. Changes detected early on and at low doses (B) consist mainly of the enlargement of lysosomes, which most likely occurs by fusion of preexisting structures and which is caused by the progressive deposition of polar lipids which adopt a concentric lamellar disposition (myelin-like structures, most commonly referred to as *myeloid bodies*); the other subcellular structures are usually well preserved. Later changes or changes observed with high doses (C) include the apparent rupture of lysosomes (with the release of myeloid bodies in the cytosol), extensive mitochondrial swelling and damage, dilatation of the endoplasmic reticulum cisternae, shedding of the apical brush-border villi, pericellular membrane discontinuities, and the occurrence of apoptotic nuclei. These alterations do not necessarily coexist in all cells. The figure is adapted from reference 76 and is based on the typical descriptions given in references 38, 40, 71, 76, 77, 127, and 138.

Synthesis and Structure of the novel aminoglycoside ACHN-490

- ACHN-490 is a derivative of sisomycin (known to be highly active but toxic)
- The modifications made provide protection against most pevalent AMEs
- Equally active against gentamicin-S and gentamicin Enterobacteriaceae and Staphylococci
- less toxic than gentamicin in in vitro and animal studies
- Indications currently tested include cUTI, HAP, cIAI, and blood stream infections

Aggen J, et al, ICAAC 2009 Poster F1-840

Extensive Safety Monitoring Focused on Nephrotoxicity and Ototoxicity showed no major effect

- Adverse Event monitoring
- Routine safety laboratory assessments
- Renal
 - Daily BUN & Cr during dosing
 - Calculated Creatinine clearance using Cockroft-Gault formula
 - Measured Creatinine clearance based on 24-hour urine collection
 - Additional GFR monitoring through lothalamate clearance
- Cochlear
 - Full Audiograms with bone conduction
 - Test range 2 to 20 kHz (normal hearing range 2 to 8 kHz)
 - Daily Otoacoustic Emission (OAE) testing during multiple dose period
- Vestibular
 - Full Electronystagmography (ENG) with calorics
 - Tests: Unilateral Weakness, Directional Preponderance, Pendulum Tracking, Fixation
 - Daily Dynamic Visual Acuity (DVA) tests during multiple dose period

- phase I
- phase II

phase III ongoing!

Refurbishing old antibiotic: 2. Novel polymyxins *?

 Colistin (Polymyxin E; discovered in 1949 and without clinical use for long) has now become the "last resource" antibiotics in the treatment of infecions caused by multi-resistant organisms...

Colistin: the revival of polymyxins for the management of multidrug-resistant gram-negative bacterial infections.

Falagas ME, Kasiakou SK.

Clin Infect Dis. 2005 May 1;40(9):1333-41. Epub 2005 Mar 22. Review. Erratum in: Clin Infect Dis. 2006 Jun 15;42(12):1819. Dosage error in article text.

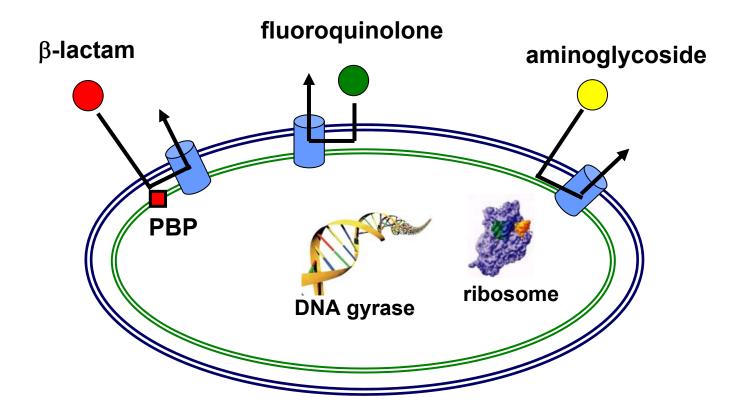

PMID: 15825037 [PubMed - indexed for MEDLINE] Free Article

Related citations

- But colistin is a fairly toxic antibiotic (nephrotoxicity), which limits the concentrations that can be safely used, and therefore, limits its activity).
- Polmyxin B is more active but more toxic ...
- Better compounds are badly needed, but the mode of action of colistin (membrane permabilization) should be retained because it ensures a fast bactericidal effect AND synergy with other antibiotics

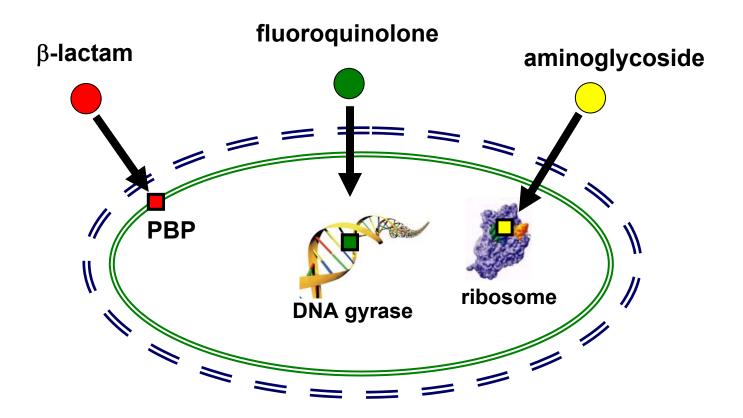

^{*} in collaboration with Northern Antibiotics, Finland

Polymyxins synergy: the rationale (1)

 Gram-negative bacteria have also efflux systems defeating the passage of drugs across the OM and explaining the low activity of many antibiotics (intrinsic resistance) and the so-called "adaptative" resistance (aminglycosides)

Polymyxins synergy: the rationale (2)

- Disrupting the OM (as colistin does) will facilitate access of the other antibiotics to their targets
- This may apply EVEN to antibiotics for which the bateria are resistant (if due to OM impermeability/efflux phenomenon)

Novel polymyxin B derivatives

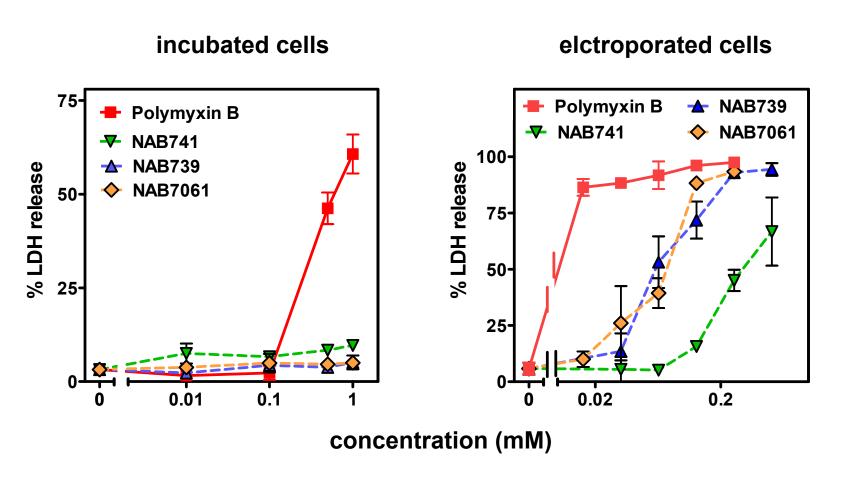

- The MIC90 of NAB739 for *E. coli* and Enterobacteriaceae are similar to those of polymyxin B (1-2 mg/L).
- NAB739 is also active against Acinetobacter baumannii, and Pseudomonas aeruginosa.
- NAB7061 and NAB741 strongly synergize the activity of antibiotics (including rifampicin, macrolides, fusidic acid and vancomycin) towards Gram (-) pathogens

Vaara et al. 2008, Antimicrob. Agents Chemother. 52:3229-3236 - Vaara et al. 2010a, Antimicrob. Agents Chemother. 54, 3341-3346 - Vaara et al. 2010b, J. Antimicrob. Chemother. 65, 942-945.

NAB compounds are less cytotoxic than polymyxin B

Temocillin revived

David M. Livermore^{1*} and Paul M. Tulkens²

¹Antibiotic Resistance Monitoring and Reference Laboratory, Health Protection Agency Centre for Infections, 61 Colindale Avenue, London NW9 5EQ, UK; ²Unité de Pharmacologie Cellulaire et Moléculaire & Centre de Pharmacie Clinique, Université Catholique de Louvain, Bruxelles, Belgium

Resistance in Gram-negative pathogens is an increasing concern, with carbapenems often appearing as the only acceptable treatment option in serious infections. Reviving older compounds that have fallen into disuse may help to alleviate this burden. Temocillin (6- α -methoxy-ticarcillin) is resistant to most if not all classical and extended-spectrum β-lactamases and to AmpC enzymes. It is also chemically stable, allowing administration by continuous infusion. Pharmacokinetic/pharmacodynamic analysis, aided by Monte-Carlo simulations, suggests a breakpoint of 8 mg/L for the registered maximum dosage of 4 g daily. Temocillin's weaknesses, explaining its limited previous use, are a lack of activity against Gram-positive organisms, anaerobes and *Pseudomonas*. In settings where these are unlikely or are covered by other agents, temocillin may be useful, potentially 'sparing' carbapenems and having little apparent potential to select for Clostridium difficile.

^{*} in collaboration with Eumedica (Belgian SME)

Temocillin in a nutshell

The α -methoxy group (arrow) in temocillin blocks access of water (W1) to the active serine (S70) of β -lactamase, thereby blocking the chain of molecular events leading to hydroysis

Matagne et al. Biochem J 1993; 293:607-11

Why is temocillin not active against *P. aeruginosa*?

Table 1. MICs of temocillin and ticarcillin against *P. aeruginosa* strains with known expression of the efflux Mex components in Mueller-Hinton broth (MHB) and in MHB supplemented with the broad spectrum efflux transporter inhibitor Phe-Arg-β-naphthylamide (PAβN; 50 μg/mL)

Disclosures

Financial support from

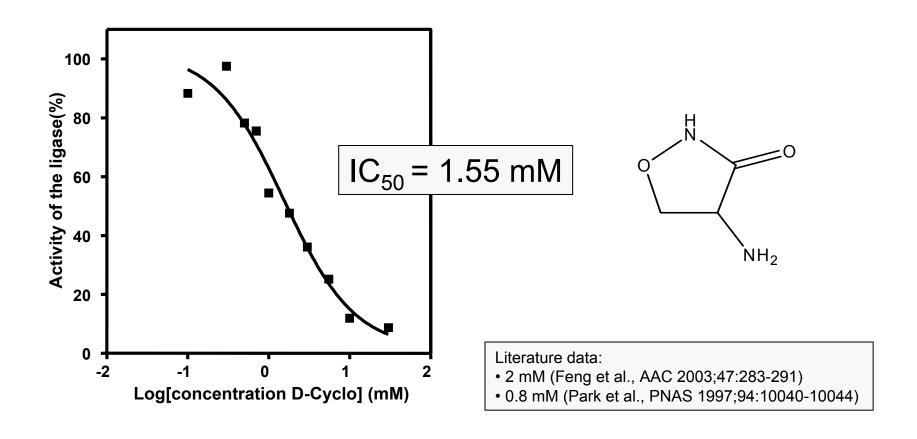

- the Belgian Fonds de la Recherche Scientifique (and other federal and regional funding agencies) for basic research on pharmacology and toxicology of antibiotics and related topics and for support to a PhD fellow (D. Das)
- The Université catholique de Louvain for personal support
- the Belgian Public Federal Service "Public Health" for "Appropriate antibiotic use" studies in General Practice
- The Pôles d'Attraction Interuniversitaire/ Interuniversitair Attractie Polen
 programme of the Belgian Federal Governement, the Région
 Bruxelloise/Brusselse Gewest and the Région Wallonne for support to postdoctoral fellows
- Collaborations with Achaogen, Northern Antibiotics, RibX, Merlion, Trius, Cerexa, Bayer, AstraZeneca, and GSK.

Back-up slides

Rationale

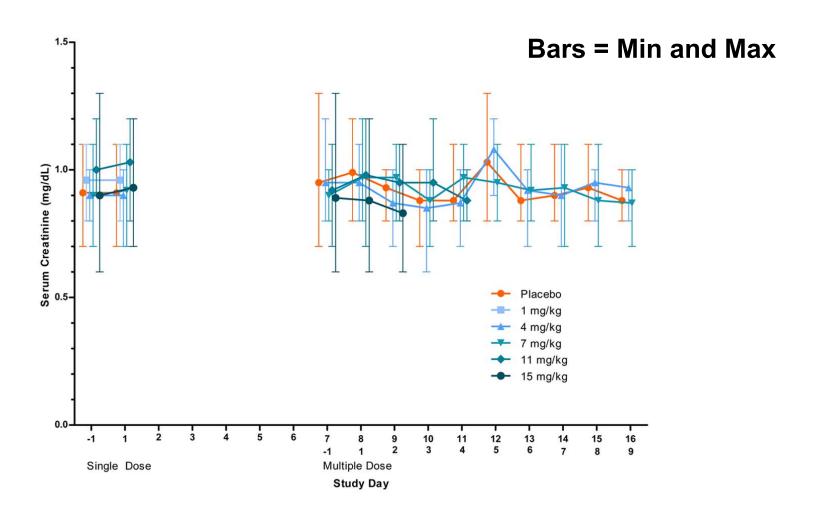

- D-Ala-D-Ala ligases are essential enzymes
- This target has been only poorly explored
 - cycloserine: poor inhibitor and toxic)
 - Phosphinates: active on the enzyme but do not penetrate in the bacteria (too polar)
- Two approaches:
 - through conventional pharmacochemical approaches (modeling around know substrate)
 - de novo modeling from analysis of the protein conformation
 - BUT always using compounds that will enter the bacteria

Inhibition of purified His-tagged D-Ala – D-Ala ligase by D-cycloserine *

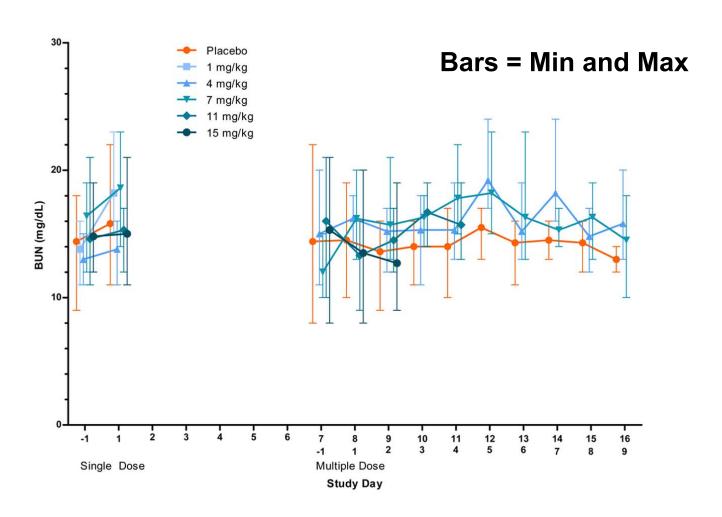

^{*} broad but weak antimicrobial activity (through inhibition of D-Ala-racemase and, to a lesser extent, D-Ala-D-Ala ligase); used as 2d/3d line drug against M. tuberculosis (MIC: 5-20 mg/L; 50-200 μM); usage limited because of CNS toxicity

Efflux and resistance

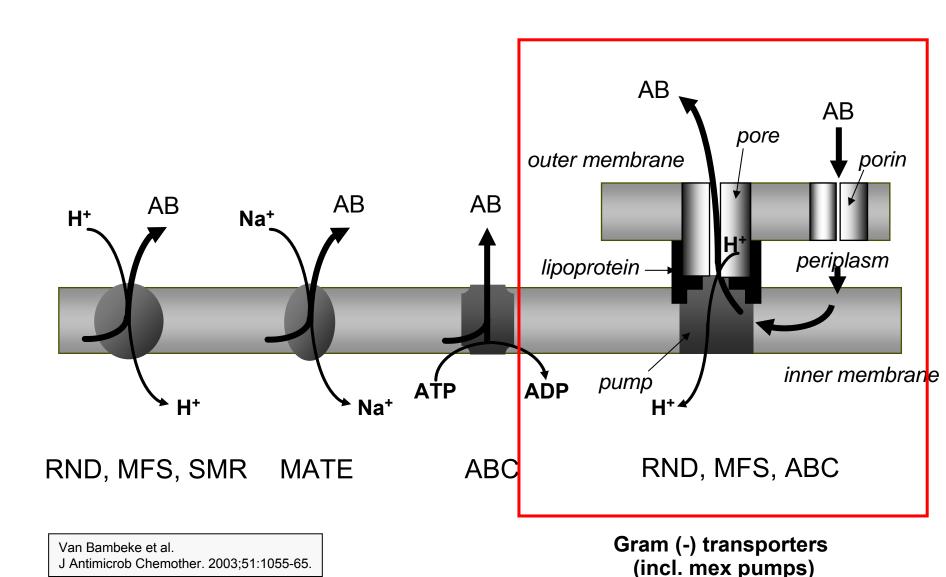

- efflux is a universal mechanism for cell protection against "toxic" membranediffusing agents
- many drugs diffuse though membranes because we made them amphiphilic to favor their diffusibility ...and become opportunistic substrates for efflux pumps
- for AB, efflux decreases the amount of drug in bacteria and impairs activity, increasing the MIC ...
- insufficient drug exposure favors the selection of less sensitive organisms

ATP Binding in SAV1866

J. Phys. Chem. B, Vol. 114, No. 48, 2010 15949

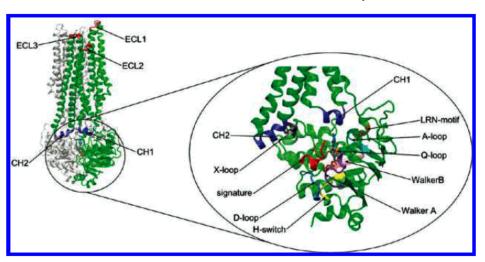

Figure 1. Ribbon representation depicting the crystal structure of the SAV1866 dimer (PDB code: 20NJ). One monomer is green, the second monomer is white. The ATP molecules located in the NBDs are represented as sticks and are colored according to the atom represented (carbon in cyan, nitrogen in blue, oxygen in red, and phosphorus in bronze). ECL and CH stand for the extracellular loops and the intracellular coupling helices. The enlarged view shows a close-up illustration of one of the NBDs and of the main motifs common to members of the ABC exporter family.

Structure-based approach: the substrate

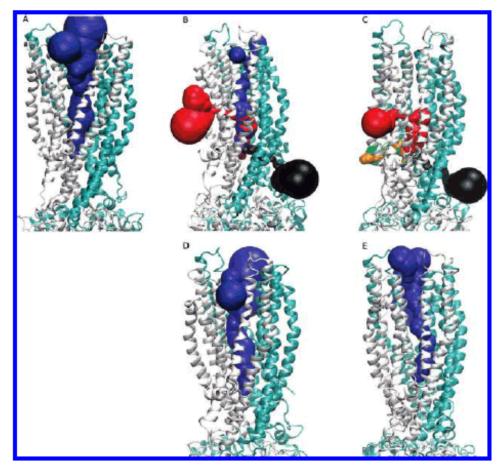

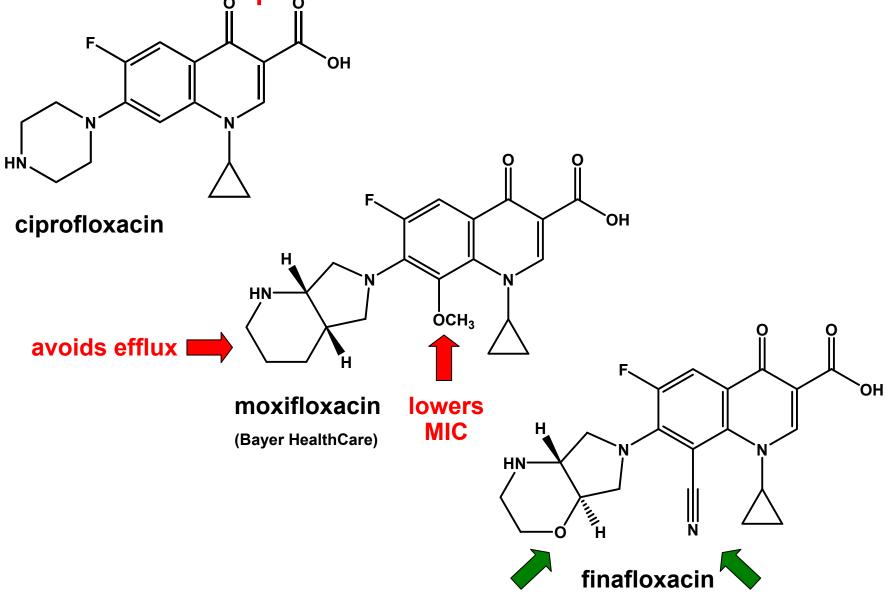

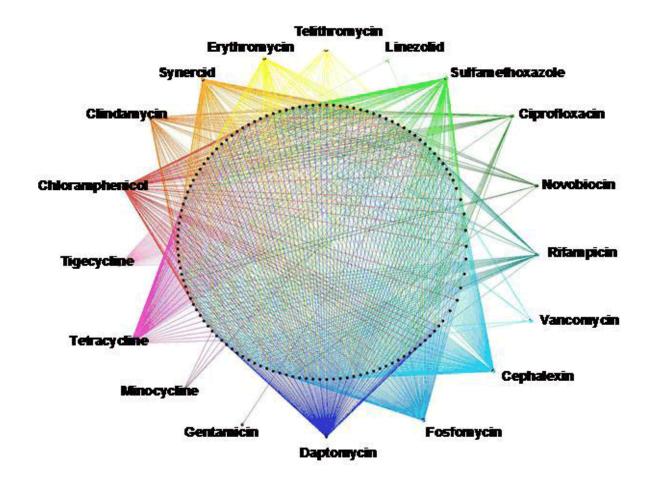

Figure 3. Dynamics of the internal TMD chamber in the nucleotide-free and the nucleotide-bound trajectories. Access paths originating at the bottom center of the TMD identified with the MOLE program⁵⁷ at 0, 40, and 80 ns of the simulation time. Upper: In the nucleotide-free trajectory. (A) At 0 ns a central path is identified that eventually splits at its extracellular extremity. (B) At 40 ns a central path persists, albeit with a much smaller radius. (C) At 80 ns, no central cavity exiting to the extracellular medium is identified anymore. Other, narrower paths exit to the cytosol and inner membrane leaflet. Lower: In the nucleotide-bound trajectory. (D) and (E) At 40 and 80 ns a central tunnel is observed. The 0 ns conformation is not shown as it is identical to that in the nucleotide-bound trajectory.

From ciprofloxacin to finafloxacin...

The connectome.... (cross-resistance)

http://wrightlab.mcmasteriidr.ca/

The resistome ...

- Resistance emergence is a natural process that has gone on for time immemorial.
 - Example: Parts of the operon mediating vancomycin resistance have been found in the permafrost layer, demonstrating the ancient nature of the problem... (many other examples of "resistance" in pre-antibiotic era)
 - > Significance: resistance was with us since ever and we will never get rid of it ...
- Horizontal gene transfer has long been considered as the main mechanism by which the resistome has been built over years
 - β-actamases, MRSA (PBP2a), Penicillin-resistant S. pneumoniae (mosaic genes), aminoglycoside-inactivating enzymes, QnR (fluoroquinolones-target protecting protein) ...
